</thead>
</table>
| 3.30c             | 190110   | OO  | Chapter "Configuring embOS/IP" updated.  
• Additional information for TCP window size configuration added.  
• Configuration switch IP_SUPPORT_TCP_DELAYED_ACK added. |
| 3.30b             | 181026   | OO  | Chapter "Core functions" updated.  
• Additional information for IP_SendEtherPacket() updated.  
Chapter "PHY drivers" updated.  
• Information for Microchip/Micrel KSZ8863 added.  
Chapter "PTP Ordinary Clock (Add-on)" updated.  
• Information about TAI time representation added.  
Chapter "RAW zero-copy interface" updated.  
• IP_RAW_ReducePayloadLen() added.  
Chapter "UDP zero-copy interface" updated.  
• IP_UDP_ReducePayloadLen() added.  
Chapter "Web server (Add-on)" updated.  
• Progress status WEBs_PROGRESS_STATUS_METHOD_URL_VER_PARSED added to structure WEBs_PROGRESS_INFO.  
• Added missing "paVFiles" member to WEBs_APPLICATION structure.  
Chapter "WebSocket (Add-on)" updated.  
• Link to IP_WEBS_WEBSOCKET_AddHook() added for better explanation of samples.  
Chapter "WiFi support" updated.  
• IP_WIFI_SECURITY_WPA_WPA2_MIXED added to IP_WIFI_CONNecT_PARAMS description. |
| 3.30              | 180709   | OO  | Chapter "Internet Protocol version 6 (IPv6) (Add-on)" updated.  
• IP_IPV6_GetIPv6Addr() added. |
| 3.30              | 180704   | OO  | Chapter "Core functions" updated.  
• IP_DisableIPv4() added.  
• Additional information for IP_AddEtherInterface() added.  
• Default values for IP_ARP_Config() added/corrected.  
Chapter "DHCP Client" updated.  
• IP_DHCPC_ConfigUniBeStartMode() added.  
Chapter "DHCP server (Add-on)" updated.  
• IP_DHCPS_SetReservedAddresses() added.  
Chapter "Internet Protocol version 6 (IPv6) (Add-on)" updated.  
• IP_ICMPV6_NDP_SetDNSLCallback() added.  
• IP_IPV6_SetGateway() added.  
Chapter "mDNS Server (Add-on)" updated.  
• Added "Flags" member to IP_DNS_SERVER_SD_CONFIG structure.  
Chapter "MQTT client (Add-on)" updated.  
• Added information for publisher and subscriber using the same connection.  
• IP_MQTT_CLIENT_Exec() added.  
• IP_MQTT_CLIENT_IsClientConnected() added.  
• IP_MQTT_CLIENT_ParsePublish() added.  
Chapter "WiFi support" updated.  
• IP_WIFI_AddClientNotificationHook() added.  
Chapter "Web server (Add-on)" updated.  
• IP_WEBS_SetErrorPageCallback() added.  
• IP_WEBS_AddProgressHook() added.  
• IP_WEBS_HEADER_AddFieldHook() added.  
• IP_WEBS_HEADER_CopyData() added.  
• IP_WEBS_HEADER_GetFindToken() added.  
• IP_WEBS_HEADER_SetCustomFields() added.  
Chapter "WebSocket (Add-on)" updated.  
• IP_WEBSOCKET_InitClient() added. |
| 3.22a             | 170801   | OO  | Chapter "Core functions" updated.  
• IP_NI_PauseRxInt() added.  
Chapter "Discovery Add-on" updated.  
• Added information to structures IP_DNS_SERVER_A and IP_DNS_SERVER_AAAA when using IP address 0. |
| 3.22              | 170728   | OO  | Chapter "Core functions" updated.  
• IP_DNS_ResolveHostEx() added. |

| 2.02a             | 0    | 120514 OO | Chapter "AutoIP" added.  
Chapter "Address Collision Detection" added. |
| 2.02             | 0    | 120507 OO | Documentation updated for embOS/IP V2 stack.  
Chapter "API functions" updated.  
• "IP_GetRawPacketInfo()" added.  
• "IP_ICMP_Add()" added.  
• "IP_TCP_Add()" added.  
• "IP_UDP_Add()" added.  
Chapter "PPP" added.  
Chapter "NetBIOS" added. |
| 1.60              | 0    | 100324 SK | Chapter "API functions" updated.  
• "IP_SetSupportedDuplexModes()" added.  
Chapter "FTP client" added.  
Minor updates and corrections. |
| 1.58              | 0    | 100204 SK | Chapter "SMTP client" updated.  
Chapter "Configuration" updated.  
• Section "Required buffers" updated.  
Minor updates and corrections. |
| 1.56              | 0    | 090710 SK | Chapter "API functions" updated.  
• "IP_DNSC_SetMaxTLL()" added.  
Chapter "Configuring embOS/IP" updated.  
Macro "IP_TCP_ACCEPT_CHECKSUM_FFFF" added. |
| 1.54b             | 0    | 090603 SK | Chapter "Web server (Add-on)" updated.  
• "IP_WEBS_Process()" updated.  
• "IP_WEBS_ProcessLast()" added.  
• "IP_WEBS_OnConnectionLimit()" updated. |
| 1.54a             | 1    | 090520 SK | Chapter "API functions" updated.  
• IP_GetAddrMask() updated.  
• IP_GetGNMask() updated.  
• IP_GetIPMask() updated.  
Chapter "Web server (Add-on)" updated.  
• Section "Changing the file system type" added.  
• Section "IP_WEBS_SetFileInfoCallback" updated. |
| 1.54a             | 0    | 090508 SK | Chapter "Web server (Add-on)" updated.  
• IP_WEBS_GetNumParas() added.  
• IP_WEBS_GetParaValue() added.  
• IP_WEBS_DecodeAndCopyStr() added.  
• IP_WEBS_DecodeString() added.  
• IP_WEBS_SetFileInfoCallback() added.  
• IP_WEBS_CompareFilenameExt() added.  
Section "Dynamic content" added  
Section "Common Gateway interface" moved into section "Dynamic content".  
Chapter "Socket interface"  
• getpeername() corrected.  
Chapter "Network interface drivers" updated. |
| 1.54              | 0    | 090504 SK | Chapter "UDP zero-copy" updated. |

|                   |         |    | • IP_ConfTCPspace() added.  

About this document

Assumptions
This document assumes that you already have a solid knowledge of the following:

- The software tools used for building your application (assembler, linker, C compiler).
- The C programming language.
- The target processor.
- DOS command line.

If you feel that your knowledge of C is not sufficient, we recommend The C Programming Language by Kernighan and Richie (ISBN 0--13--1103628), which describes the standard in C programming and, in newer editions, also covers the ANSI C standard.

How to use this manual
This manual explains all the functions and macros that the product offers. It assumes you have a working knowledge of the C language. Knowledge of assembly programming is not required.

Typographic conventions for syntax
This manual uses the following typographic conventions:

<table>
<thead>
<tr>
<th>Style</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>Body</td>
<td>Body text.</td>
</tr>
<tr>
<td>Keyword</td>
<td>Text that you enter at the command prompt or that appears on the display (that is system functions, file- or pathnames).</td>
</tr>
<tr>
<td>Parameter</td>
<td>Parameters in API functions.</td>
</tr>
<tr>
<td>Sample</td>
<td>Sample code in program examples.</td>
</tr>
<tr>
<td>Sample comment</td>
<td>Comments in program examples.</td>
</tr>
<tr>
<td>Reference</td>
<td>Reference to chapters, sections, tables and figures or other documents.</td>
</tr>
<tr>
<td>GUIElement</td>
<td>Buttons, dialog boxes, menu names, menu commands.</td>
</tr>
<tr>
<td>Emphasis</td>
<td>Very important sections.</td>
</tr>
</tbody>
</table>
# Table of contents

1 Introduction to embOS/IP ................................................................................................................... 39
  1.1 What is embOS/IP .......................................................................................................................... 40
  1.2 Features ....................................................................................................................................... 41
  1.3 Basic concepts ............................................................................................................................... 42
    1.3.1 embOS/IP structure .................................................................................................................. 42
    1.3.2 Encapsulation .......................................................................................................................... 43
  1.4 Tasks and interrupt usage .............................................................................................................. 44
  1.5 Background information ................................................................................................................. 47
    1.5.1 Components of an Ethernet system ......................................................................................... 47
      1.5.1.1 MII / RMII: Interface between MAC and PHY ............................................................... 48
  1.6 Further reading .............................................................................................................................. 50
    1.6.1 Request for Comments (RFC) ................................................................................................. 50
    1.6.2 Related books .......................................................................................................................... 51
  1.7 Development environment (compiler) ............................................................................................ 52

2 Running embOS/IP on target hardware ........................................................................................... 53
  2.1 Step 1: Open an embOS start project ............................................................................................ 54
  2.2 Step 2: Adding embOS/IP to the start project .............................................................................. 55
  2.3 Step 3: Build the project and test it ............................................................................................... 57

3 Example applications ....................................................................................................................... 59
  3.1 Overview ....................................................................................................................................... 60
    3.1.1 embOS/IP DNS client (IP_DNSClient.c) .................................................................................. 60
    3.1.2 embOS/IP non-blocking connect (IP_NonBlockingConnect.c) ................................................. 60
    3.1.3 embOS/IP ping (IP_Ping.c) ....................................................................................................... 61
    3.1.4 embOS/IP shell (IP_SHELL_Start.c) ........................................................................................ 61
    3.1.5 embOS/IP simple server (IP_SimpleServer.c) ....................................................................... 62
    3.1.6 embOS/IP speed client (IP_SpeedClient_TCP.c) ..................................................................... 62
      3.1.6.1 Running the embOS/IP speed client .................................................................................. 62
    3.1.7 embOS/IP start (IP_Start.c) ..................................................................................................... 63

Chapter 1

Introduction to embOS/IP

This chapter provides an introduction to using embOS/IP. It explains the basic concepts behind embOS/IP.
1.1 What is embOS/IP

embOS/IP is a CPU-independent TCP/IP stack.

embOS/IP is a high-performance library that has been optimized for speed, versatility and small memory footprint.
1.2 Features

embOS/IP is written in ANSI C and can be used on virtually any CPU.

Some features of embOS/IP:
- Standard socket interface.
- High performance.
- Small footprint.
- No configuration required.
- Runs "out-of-the-box".
- Very simple network interface driver structure.
- Works seamlessly with embOS in multitasking environment.
- Zero data copy for ultra fast performance.
- Non-blocking versions of all functions.
- Connections limited only by memory availability.
- Delayed ACKs.
- Handling gratuitous ARP packets
- Support for VLAN
- BSD style "keep-alive" option.
- Support for messages and warnings in debug build.
- Drivers for most common Ethernet controllers available.
- Support for driver side (hardware) checksum computation.
- Royalty-free.
1.3 Basic concepts

1.3.1 embOS/IP structure

embOS/IP is organized in different layers, as shown in the following illustration.

![Layer Diagram]

A short description of each layer’s functionality follows below.

**Application layer**

The application layer is the interface between embOS/IP and the user application. It uses the embOS/IP API to transmit data over an TCP/IP network. The embOS/IP API provides functions in BSD (Berkeley Software Distribution) socket style, such as `connect()`, `bind()`, `listen()`, etc.

**Transport layer**

The transport layer provides end-to-end communication services for applications. The two relevant protocols of the Transport layer protocol are the Transmission Control Protocol (TCP) and the User Datagram Protocol (UDP). TCP is a reliable connection-oriented transport service. It provides end-to-end reliability, resequencing, and flow control. UDP is a connectionless transport service.

**Internet layer**

All protocols of the transport layer use the Internet Protocol (IP) to carry data from source host to destination host. IP is a connectionless service, providing no end-to-end delivery guarantees. IP datagrams may arrive at the destination host damaged, duplicated, out of order, or not at all. The transport layer is responsible for reliable delivery of the datagrams when it is required. The IP protocol includes provision for addressing, type-of-service specification, fragmentation and reassembly, and security information.

**Link layer**

The link layer provides the implementation of the communication protocol used to interface to the directly-connected network. A variety of communication protocols have been developed and standardized. The most commonly used protocol is Ethernet (IEEE 802.3). In this version of embOS/IP only Ethernet is supported.
### 1.3.2 Encapsulation

The four layers structure is defined in [RFC 1122]. The data flow starts at the application layer and goes over the transport layer, the network layer, and the link layer. Every protocol adds a protocol-specific header and encapsulates the data and header from the layer above as data. On the receiving side, the data will be extracted in the complementary direction. The opposed protocols do not know which protocol on the above and below layers are used.

The following illustration shows the encapsulation of data within an UDP datagram within an IP packet.
CHAPTER 1

1.4 Tasks and interrupt usage

embOS/IP can be used in an application in three different ways.

- One task dedicated to the stack (IP_Task)
- Two tasks dedicated to the stack (IP_Task, IP_RxTask)
- Zero tasks dedicated to the stack (Superloop)

The default task structure is one task dedicated to the stack. The priority of the management task IP_Task should be higher than the priority of all application tasks that use the stack to allow optimal performance. The IP_RxTask (if available) needs to run at the highest single task priority of all IP related task as it is an interrupt moved into a task.

Task priorities

Task priorities are independent from other task priorities. However as soon as a task calls an IP API it should follow these priority rules for best performance of the stack:

1. The IP_RxTask (if used at all) needs to have the highest single priority of all tasks that make use of the IP API, having a higher priority than the IP_Task.
2. The IP_Task should have a higher task priority than any other task that makes use of the IP API. It needs to have a lower priority than the IP_RxTask (if used at all).
3. All tasks that make use of the IP API should use a task priority below the IP_Task to allow optimal performance.

Task priorities for tasks not using the IP API can be freely chosen.

One task dedicated to the stack

To use one task dedicated to the stack is the simplest way to use the TCP/IP stack. It is called IP_Task and handles housekeeping operations, resending and handling of incoming packets. The “Read packet” operation is performed from within the ISR. Because the “Read packet” operation is called directly from the ISR, no additional task is required. The length of the interrupt latency will be extended for the time period which is required to process the “Read packet” operation. Refer to IP_Task on page 154 for more information and an example about how to include the IP_Task into your embOS project.
Two tasks dedicated to the stack

Two tasks are dedicated to the stack. The first task is called the IP_Task and handles housekeeping operations, resends, and handling of incoming packets. The second is called IP_RxTask and handles the "Read packet" operation. IP_RxTask is waked up from the interrupt service routine, if new packets are available. The interrupt latency is not extended, because the "Read packet" operation has been moved from the interrupt service routine to IP_RxTask. Refer to IP_Task on page 154 and IP_RxTask on page 155 for more information. IP_RxTask has to have a higher priority than IP_Task as it is treated as interrupt in task form and might not be interrupted by IP_Task or any other IP task.
Zero tasks dedicated to the stack (Superloop)

embOS/IP can also be used without any additional task for the stack, if an application task calls `IP_Exec()` periodically. The “Read packet” operation is performed from within the ISR. Because the “Read packet” operation is called directly from the ISR, no additional task is required. The length of the interrupt latency will be extended for the time period which is required to process the “Read packet” operation.
1.5 Background information

1.5.1 Components of an Ethernet system

Main parts of an Ethernet system are the Media Access Controller (MAC) and the Physical device (PHY). The MAC handles generating and parsing physical frames and the PHY handles how this data is actually moved to or from the wire.

MCUs with integrated MAC

Some modern MCUs (for example, the ATMEL SAM7X or the ST STR912) include the MAC and use the internal RAM to store the Ethernet data. The following block diagram illustrates such a configuration.

External Ethernet controllers with MAC and PHY

Chips without integrated MAC can use fully integrated single chip Ethernet MAC controller with integrated PHY and a general processor interface. The following schematic illustrates such a configuration.
1.5.1.1 MII / RMII: Interface between MAC and PHY

The MAC communicates with the PHY via the Media Independent Interface (MII) or the Reduced Media Independent Interface (RMII). The MII is defined in IEEE 802.3u. The RMII is a subset of the MII and is defined in the RMI specification. The MII/RMII can handle control over the PHY which allows for selection of such transmission criteria as line speed, duplex mode, etc.

In theory, up to 32 PHYs can be connected to a single MAC. In praxis, this is never done; only one PHY is connected. In order to allow multiple PHYs to be connected to a single MAC, individual 5-bit addresses have to be assigned to the different PHYs. If only one PHY is connected, the embOS/IP driver automatically finds the address of it.

The standard defines 32 16-bit PHY registers. The first 6 are defined by the standard.

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMCR</td>
<td>Basic Mode Control Register</td>
</tr>
<tr>
<td>BSR</td>

<td>PHYS ID 2</td>
</tr>
<tr>
<td>ANAR</td>
<td>Auto-Negotiation Advertisement Register</td>
</tr>
<tr>
<td>LPAR</td>
<td>Link Partner Ability register</td>
</tr>
</tbody>
</table>

The drivers automatically recognize any PHY connected, no manual configuration of PHY address is required.

The MII and RMII interface are capable of both 10Mb/s and 100Mb/s data rates as described in the IEEE 802.3u standard.

The intent of the RMII is to provide a reduced pin count alternative to the IEEE 802.3u MII. It uses 2 bits for transmit (TXD0 and TXD1) and two bits for receive (RXD0 and RXD1). There is a Transmit Enable (TX_EN), a Receive Error (RX_ER), a Carrier Sense (CRS), and a 50 MHz Reference Clock (TX_CLK) for 100Mb/s data rate. The pins used by the MII and RMII interfaces are described in the following table.

<table>

1.6    Further reading

This guide explains the usage of the embOS/IP protocol stack. It describes all functions which are required to build a network application. For a deeper understanding about how the protocols of the Internet protocol suite works use the following references.

The following Request for Comments (RFC) define the relevant protocols of the Internet protocol suite and have been used to build the protocol stack. They contain all required technical specifications. The listed books are simpler to read as the RFCs and give a general survey about the interconnection of the different protocols.

1.6.1    Request for Comments (RFC)

<table>

1.6.2 Related books

1.7 Development environment (compiler)

The CPU used is of no importance; only an ANSI-compliant C compiler complying with at least one of the following international standard is required:

- ISO/IEC/ANSI 9899:1990 (C90) with support for C++ style comments (//)
- ISO/IEC 9899:1999 (C99)
- ISO/IEC 14882:1998 (C++)

If your compiler has some limitations, let us know and we will inform you if these will be a problem when compiling the software. Any compiler for 16/32/64-bit CPUs or DSPs that we know of can be used; most 8-bit compilers can be used as well.

A C++ compiler is not required, but can be used. The application program can therefore also be programmed in C++ if desired.
This chapter explains how to integrate and run embOS/IP on your target hardware. It explains this process step-by-step.

Integrating embOS/IP

The embOS/IP default configuration is preconfigured with valid values, which matches the requirements of the most applications. embOS/IP is designed to be used with embOS, SEGGER’s real-time operating system. We recommend to start with an embOS sample project and include embOS/IP into this project. We assume that you are familiar with the tools you have selected for your project (compiler, project manager, linker, etc.). You should therefore be able to add files, add directories to the include search path, and so on. In this document the SEGGER Embedded Studio is used for all examples and screenshots, but every other ANSI C toolchain can also be used. It is also possible to use make files; in this case, when we say “add to the project”, this translates into “add to the make file”.

Procedure to follow

Integration of embOS/IP is a relatively simple process, which consists of the following steps:

- Step 1: Open an embOS project and compile it.
- Step 2: Add embOS/IP to the start project
- Step 3: Compile the project
2.1 Step 1: Open an embOS start project

We recommend that you use one of the supplied embOS start projects for your target system. Compile the project and run it on your target hardware.
2.2 Step 2: Adding embOS/IP to the start project

Add all IP source files as in the IP release delivery to your project.

The Config folder includes all configuration files of embOS/IP. The configuration files are preconfigured with valid values, which match the requirements of most applications. Add the hardware configuration IP_Config_<TargetName>.c supplied with the driver shipment.

If your hardware is currently not supported, use the example configuration file and the driver template to write your own driver. The example configuration file and the driver template is located in the Sample folder.

The IP\ASM folder contains files for various CPUs and toolchains with routines optimized in assembler code. Typically only one of these files needs to be added to your project and the rest should be excluded. The optimized routines are used by overwriting a specific macro that typically can be found in Config\IP_Conf.h.

The SEGGER folder is an optional component of the embOS/IP shipment. It contains optimized MCU and/or compiler specific files, for example a special memcopy function.

BSP support

IP drivers need hardware setting from the BSP file (like port settings for example). Some older driver are supplied with BSP.c and BSP.h that need to replace the one supplied with embOS shipment.

Newer and updated drivers have a separate BSP_IP.c file instead.

Depending on your case, either replace BSP.c and BSP.h of your embOS start project or add BSP_IP.c.

Configuring the include path

The include path is the path in which the compiler looks for include files. In cases where the included files (typically header files, .h) do not reside in the same directory as the C file to compile, an include path needs to be set. In order to build the project with all added files, you will need to add the IP directories to your include path.
Select the start application

For quick and easy testing of your embOS/IP integration, start with the code found in the folder Application. Add one of the applications to your project (for example IP_SimpleServer.c).
2.3 Step 3: Build the project and test it

Build the project. It should compile without errors and warnings. If you encounter any problem during the build process, check your include path and your project configuration settings. To test the project, download the output into your target and start the application.

By default, ICMP is activated. This means that you could ping your target. Open the command line interface of your operating system and enter `ping <TargetAddress>`, to check if the stack runs on your target. The target should answer all pings without any error.

![Command Line Output]

Chapter 3

Example applications

In this chapter, you will find a description of each embOS/IP example application.
3.1 Overview

Various example applications for embOS/IP are supplied. These can be used for testing the correct installation and proper function of the device running embOS/IP.

The following start application files are provided:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_DNSClient.c</td>
<td>Demonstrates the use of the integrated DNS client.</td>
</tr>
<tr>
<td>IP_NonBlockingConnect.c</td>
<td>Demonstrates how to connect to a server using non-blocking sockets.</td>
</tr>
<tr>
<td>IP_Ping.c</td>
<td>Demonstrates how to send ICMP echo requests and how to process ICMP replies in application.</td>
</tr>
<tr>
<td>IP_SHELL_Start.c</td>
<td>Demonstrates using the IP-shell to diagnose the IP stack.</td>
</tr>
<tr>
<td>IP_SimpleServer.c</td>
<td>Demonstrates setup of a simple server which simply sends back the target system tick for every character received.</td>
</tr>
<tr>
<td>IP_SpeedClient_TCP.c</td>
<td>Demonstrates the TCP send and receive performance of the device running embOS/IP.</td>
</tr>
<tr>
<td>IP_Start.c</td>
<td>Demonstrates use of the IP stack without any server or client program. To ping the target, use the command line: <code>ping &lt;target-ip&gt;</code> where <code>&lt;target-ip&gt;</code> represents the IP address of the target, which depends on the configuration and is usually 192.168.2.252 if the DHCP client is not enabled.</td>
</tr>
<tr>
<td>IP_UDPDiscover.c</td>
<td>Demonstrates setup of a simple UDP application which replies to UDP broadcasts. The application sends an answer for every received discover packet. The related host application sends discover packets as UDP broadcasts and waits for the feedback of the targets which are available in the subnet.</td>
</tr>
<tr>
<td>IP_UDPDiscover_ZeroCopy.c</td>
<td>Demonstrates setup of a simple UDP application which replies to UDP broadcasts. The application uses the the embOS/IP zero-copy interface. It sends an answer for every received discover packet. The related host application sends discover packets as UDP broadcasts and waits for the feedback of the targets which are available in the subnet.</td>
</tr>
</tbody>
</table>

The example applications for the target-side are supplied in source code in the Application directory.

3.1.1 embOS/IP DNS client (IP_DNSClient.c)

The embOS/IP DNS client resolves a hostname (for example, `segger.com`) to an IP address and outputs the resolved address via terminal I/O.

3.1.2 embOS/IP non-blocking connect (IP_NonBlockingConnect.c)

The embOS/IP non-blocking connect sample demonstrates how to connect to a server using non-blocking sockets. The target tries to connect to TCP server with an non-blocking socket. The sample can be used with any TCP server independent of the application which is listening on the port. The client only opens a TCP connection to the server and closes it
without any further communication. The terminal I/O output in your debugger should be similar to the following out:

```plaintext
Connecting using non-blocking socket...
Successfully connected after 2ms!
1 of 1 tries were successful.

Connecting using non-blocking socket...
Successfully connected after 1ms!
2 of 2 tries were successful.
```

### 3.1.3 embOS/IP ping (IP_Ping.c)

The embOS/IP ping sample demonstrates how to send ICMP echo requests and how to process received ICMP packets in your application. A callback function is implemented which outputs a message if an ICMP echo reply or an ICMP echo request has been received.

To test the embOS/IP ICMP implementation, you have to perform the following steps:

1. **Customize the Local defines, configurable section of IP_Ping.c.** Change the macro `HOST_TO_PING` according to your configuration. For example, if the Windows host PC which you want to ping use the IP address 192.168.5.15, change the `HOST_TO_PING` macro to `0xC0A8050F`.
2. **Open the command line interface and enter:**

   ```plaintext
   ping [IP_ADDRESS_OF_YOUR_TARGET_RUNNING_EMBOSIP]
   ```

   The terminal I/O output in your debugger should be similar to the following out:

   ```plaintext
   ICMP echo reply received!
   ICMP echo request received!
   ICMP echo reply received!
   ICMP echo reply received!
   ICMP echo reply received!
   ICMP echo reply received!
   ICMP echo request received!
   ICMP echo reply received!
   ICMP echo reply received!
   ```

### 3.1.4 embOS/IP shell (IP_SHELL_Start.c)

The embOS/IP shell server is a task which opens TCP-port 23 (telnet) and waits for a connection. The actual shell server is part of the stack, which keep the application program nice and small. The shell server task can be added to any application and should be used to retrieve status information while the target is running. To connect to the target, use the command line: `telnet <target-ip>` where `<target-ip>` represents the IP address of the target, which depends on the configuration and is usually 192.168.2.252 if the DHCP client is not enabled.
3.1.5 **embOS/IP simple server (IP_SimpleServer.c)**

Demonstrates setup of a simple server which simply sends back the target system tick for every character received. It opens TCP-port 23 (telnet) and waits for a connection. To connect to the target, use the command line: `telnet <target-ip>` where `<target-ip>` represents the IP address of the target, which depends on the configuration and is usually 192.168.2.252 if the DHCP client is not enabled.

3.1.6 **embOS/IP speed client (IP_SpeedClient_TCP.c)**

The embOS/IP speed client is a small application to detect the TCP send and receive performance of embOS/IP on your hardware.

3.1.6.1 **Running the embOS/IP speed client**

To test the embOS/IP performance, you have to perform the following steps:

1. Start the Windows speed test server. The example application for the host-side is supplied as executable and in source code in the `Windows\SpeedTestServer\` directory. To run the speed test server, simply start the executable, for example by double-clicking it or open the supplied Visual C project and compile and start the application.
2. Add `IP_SpeedClient.c` to your project.
3. Customize the Local defines, configurable section of `IP_SpeedClient.c`. Change the macro `SERVER_IP_ADDR` according to your configuration. For example, if the Windows host PC running the speed test server uses the IP address 192.168.5.15, change the `SERVER_IP_ADDR` macro to 0xC0A8050F. If you have changed the port which the Windows host application uses to listen, change the macro `SERVER_PORT` accordingly.
4. Build and download the speed client into your target. The target connects to the server and starts the transmission.
3.1.7  embOS/IP start (IP_Start.c)

Demonstrates use of the IP stack without any server or client program. To ping the target, use the command line: ping <target-ip> where <target-ip> represents the IP address of the target, which depends on the configuration and is usually 192.168.2.252 if the DHCP client is not enabled.

3.1.8  embOS/IP UDP discover (IP_UDPDiscover.c / IP_UDPDiscover_ZeroCopy.c)

To test the embOS/IP UDP discover example, you have to perform the following steps:

1. Start the Windows UDP discover example application. The example application for the host-side is supplied as executable and in source code in the Windows\UDPDiscover\ directory. To run the UDP discover example, simply start the executable, for example by double-clicking it or open the supplied Visual C project and compile and start the application.
2. Add IP_UDPDiscover.c to your project.
3. Customize the Local defines, configurable section of IP_UDPDiscover.c. By default, the example uses port 50020. If you have changed the port that the Windows host application uses, change the macro PORT accordingly.
4. Build and download the UDP discover example into your target. The target sends an answer for every received discover packet. The related host application sends discover packets as UDP broadcasts and waits for the feedback of the targets which are available in the subnet.
Chapter 4

Core functions

In this chapter, you will find a description of each embOS/IP core function.
## 4.1 API functions

The table below lists the available API functions within their respective categories.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configuration functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_AddBuffers()</td>
<td>Adds buffers to the TCP/IP stack.</td>
</tr>
<tr>
<td>IP_AddEtherInterface()</td>
<td>Adds an Ethernet interface to the stack.</td>
</tr>
<tr>
<td>IP_AddVirtEtherInterface()</td>
<td>Adds a virtual interface to the stack that uses a hardware interface for communication.</td>
</tr>
<tr>
<td>IP_AddLoopbackInterface()</td>
<td>Adds a loopback interface to the stack.</td>
</tr>
<tr>
<td>IP_AddMemory()</td>
<td>This function is called from the application to add additional memory to the stack.</td>
</tr>
<tr>
<td>IP_AllowBackPressure()</td>
<td>Allows back pressure if the driver supports this feature.</td>
</tr>
<tr>
<td>IP_AssignMemory()</td>
<td>Assigns memory to the stack.</td>
</tr>
<tr>
<td>IP_ARP_ConfigAgeout()</td>
<td>Configures the timeout for cached ARP entries.</td>
</tr>
<tr>
<td>IP_ARP_ConfigAgeoutNoReply()</td>
<td>Configures the timeout for an ARP entry that has been added due to sending an ARP request to the network that has not been answered yet.</td>
</tr>
<tr>
<td>IP_ARP_ConfigAgeoutSniff()</td>
<td>Configures the age out value for ARP entries, which we have created by looking up addresses of received IP packets.</td>
</tr>
<tr>
<td>IP_ARP_ConfigAllowGratuitousARP()</td>
<td>Configures if gratuitous ARP packets from other network members are allowed to update the ARP cache.</td>
</tr>
<tr>
<td>IP_ARP_ConfigMaxPending()</td>
<td>Configures the maximum number packets that can be queued waiting for an ARP reply.</td>
</tr>
<tr>
<td>IP_ARP_ConfigMaxRetries()</td>
<td>Configures how often an ARP request is resent before considering the request failed.</td>
</tr>
<tr>
<td>IP_ARP_ConfigNumEntries()</td>
<td>Configures the maximum number of possible entries in the ARP cache.</td>
</tr>
<tr>
<td>IP_BSP_SetAPI()</td>
<td>Sets an API to be used for BSP related abstraction like initializing hardware and installing interrupt handlers.</td>
</tr>
<tr>
<td>IP_ConfigMaxIFaces()</td>
<td>Configures the maximum number of interfaces that can be added to the system.</td>
</tr>
<tr>
<td>IP_ConfigNumLinkDownProbes()</td>
<td>Configures the number of continuous link down probes to take before the stack accepts the link down status.</td>
</tr>
<tr>
<td>IP_ConfigNumLinkUpProbes()</td>
<td>Configures the number of continuous link up probes to take before the stack accepts the link up status.</td>
</tr>
<tr>
<td>IP_ConfigOffCached2Uncached()</td>
<td>Configures the offset from a cached memory area to its uncached equivalent for uncached access.</td>
</tr>
<tr>
<td>IP_ConfigTCPSpace()</td>
<td>Configures the size of the TCP send and receive window size.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_DisableIPRxChecksum()</td>
<td>Disables checksum verification of the checksum in the IP header for incoming packets.</td>
</tr>
<tr>
<td>IP_DisableIPv4()</td>
<td>Disables IPv4 in the stack as good as possible.</td>
</tr>
<tr>
<td>IP_CACHE_SetConfig()</td>
<td>Configures cache related functionality that might be required by the stack for several purposes such as cache handling in drivers.</td>
</tr>
<tr>
<td>IP_DNS_GetServer()</td>
<td>Retrieves the first DNS server configured of the first interface.</td>
</tr>
<tr>
<td>IP_DNS_GetServerEx()</td>
<td>Retrieves a DNS server configured for an interface.</td>
</tr>
<tr>
<td>IP_DNS_ResolveHostEx()</td>
<td>Sends a query to the DNS server.</td>
</tr>
<tr>
<td>IP_DNS_SendDynUpdate()</td>
<td>Build a dynamic update request.</td>
</tr>
<tr>
<td>IP_DNS_SetTSIGContext()</td>
<td>Set the TSIG signature context with the parameters needed to perform Secured Dynamic Updates signed with TSIG.</td>
</tr>
<tr>
<td>IP_DNS_SetMaxTTL()</td>
<td>Sets the maximum Time To Live (TTL) of a DNS entry in seconds.</td>
</tr>
<tr>
<td>IP_DNS_SetServer()</td>
<td>Sets the DNS server address of the first interface.</td>
</tr>
<tr>
<td>IP_DNS_SetServerEx()</td>
<td>Sets the IP address of the available DNS servers for an interface.</td>
</tr>
<tr>
<td>IP_MDNS_ResolveHost()</td>
<td>Sends a query using Multicast DNS.</td>
</tr>
<tr>
<td>IP_EnableIPRxChecksum()</td>
<td>Enables the IP Rx checksum calculation in the IP header for incoming packets.</td>
</tr>
<tr>
<td>IP_GetMaxAvailPacketSize()</td>
<td>Asks the stack for the maximum available free packet size that can then be allocated.</td>
</tr>
<tr>
<td>IP_GetMTU()</td>
<td>Retrieves the configured TCP MTU size for an interface.</td>
</tr>
<tr>
<td>IP_GetPrimaryIFace()</td>
<td>Retrieves the currently set primary interface index.</td>
</tr>
<tr>
<td>IP_ICMP_Add()</td>
<td>Adds ICMP Protocol function to the stack.</td>
</tr>
<tr>
<td>IP_ICMP_DisableRxChecksum()</td>
<td>Disables the ICMP Rx checksum calculation.</td>
</tr>
<tr>
<td>IP_ICMP_EnableRxChecksum()</td>
<td>Enables the ICMP Rx checksum calculation.</td>

### Configuration functions (IP fragmentation)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_FRAGMENT_ConfigRx()</td>
<td>Modifies the embOS/IP default settings for IPv4 fragmentation.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_FRAGMENT_Enable()</td>
<td>Initializes the required variables and adds a timer to the stack to handle outdated fragment queues.</td>
</tr>
<tr>
<td>IP_IPV6_FRAGMENT_ConfigRx()</td>
<td>Modifies the default settings for IPv6 fragmentation.</td>
</tr>
<tr>
<td>IP_IPV6_FRAGMENT_Enable()</td>
<td>Initializes the required variables and adds a timer to the stack to handle outdated fragment queues.</td>
</tr>
</tbody>
</table>

**Management functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_DeInit()</td>
<td>Deinitializes the TCP/IP stack.</td>
</tr>
<tr>
<td>IP_Init()</td>
<td>Initializes the TCP/IP stack.</td>
</tr>
<tr>
<td>IP_Task()</td>
<td>Main task for starting the stack.</td>
</tr>
<tr>
<td>IP_RxTask()</td>
<td>The task reads all available packets from the network interface and sleeps until a new packet is received.</td>
</tr>
<tr>
<td>IP_Exec()</td>
<td>Checks if the driver has received a packet and handles timers.</td>
</tr>
</tbody>
</table>

**Network interface configuration and handling functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_NI_AddPTPDriver()</td>
<td>Adds a PTP driver for HW timestamp support.</td>
</tr>
<tr>
<td>IP_NIClrBPmembership()</td>
<td>Disables usage of back pressure (sending a jam signal to signal when we run into a shortage where the hardware can not receive more data).</td>
</tr>
<tr>
<td>IP_NI_ConfigPoll()</td>
<td>Select polled mode for the network interface.</td>
</tr>
<tr>
<td>IP_NI_ForceCaps()</td>
<td>Allows to force capabilities to be set for an interface.</td>
</tr>
<tr>
<td>IP_NI_SetBPmembership()</td>
<td>Enables usage of back pressure (sending a jam signal to signal when we run into a shortage where the hardware can not receive more data).</td>
</tr>
<tr>
<td>IP_NI_SetTxBufferSize()</td>
<td>Sets the size of the Tx buffer of the network interface.</td>
</tr>
</tbody>
</table>

**PHY configuration functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_NI_ConfigPHYAddr()</td>
<td>Configure the PHY Addr.</td>
</tr>
<tr>
<td>IP_NI_ConfigPHYMode()</td>
<td>Configure the PHY mode.</td>
</tr>
<tr>
<td>IP_PHY_AddDriver()</td>
<td>Adds a PHY driver and assigns it to an interface.</td>
</tr>
<tr>
<td>IP_PHY_AddResetHook()</td>
<td>This function adds a hook function to the IP_HOOK_ON_PHY_RESET list.</td>
</tr>
<tr>
<td>IP_PHY_ConfigAddr()</td>
<td>Configures the PHY address to use.</td>
</tr>
<tr>
<td>IP_PHY_ConfigAltAddr()</td>
<td>Sets a list of PHY addresses that can alternately be checked for the link state.</td>
</tr>
<tr>
<td>IP_PHY_ConfigGigabitSupport()</td>
<td>Configures if the MAC supports Gigabit Ethernet.</td>
</tr>
<tr>
<td>IP_PHY_ConfigSupportedModes()</td>
<td>Configures the duplex and speed modes that shall be supported.</td>
</tr>
<tr>
<td>IP_PHY_ConfigUseStaticFilters()</td>
<td>Tells the stack if using PHY static MAC filter is allowed.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_PHY_DisableCheck()</td>
<td>Disables PHY checks for all interfaces.</td>
</tr>
<tr>
<td>IP_PHY_DisableCheckEx()</td>
<td>Disables PHY checks for one interface.</td>
</tr>
<tr>
<td>IP_PHY_ReInit()</td>
<td>Re-initializes the PHY.</td>
</tr>
<tr>
<td>IP_PHY_SetWdTimeout()</td>
<td>Sets the watchdog timeout for watching if the PHY reached an unstable state.</td>
</tr>
</tbody>
</table>

**Statistics functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_STATS_EnableIFaceCounters()</td>
<td>Enables statistic counters for a specific interface.</td>
</tr>
<tr>
<td>IP_STATS_GetIFaceCounters()</td>
<td>Retrieves a pointer to the statistic counters for a specific interface.</td>
</tr>
<tr>
<td>IP_STATS_GetLastLinkStateChange()</td>
<td>Retrieves the tick count when an interface entered its current state.</td>
</tr>
<tr>
<td>IP_STATS_GetRxBytesCnt()</td>
<td>Retrieves the number of bytes received on an interface.</td>
</tr>
<tr>
<td>IP_STATS_GetRxDiscardCnt()</td>
<td>Retrieves the number of packets received but discarded although they were O.K.</td>
</tr>
<tr>
<td>IP_STATS_GetRxErrCnt()</td>
<td>Retrieves the number of receive errors.</td>
</tr>
<tr>
<td>IP_STATS_GetRxNotUnicastCnt()</td>
<td>Retrieves the number of packets received on an interface that were not unicasts.</td>
</tr>
<tr>
<td>IP_STATS_GetRxUnicastCnt()</td>
<td>Retrieves the number of unicast packets received on an interface.</td>
</tr>
<tr>
<td>IP_STATS_GetRxUnknownProtoCnt()</td>
<td>Retrieves the number of unknown protocols received.</td>
</tr>
<tr>
<td>IP_STATS_GetTxBytesCnt()</td>
<td>Retrieves the number of bytes sent on an interface.</td>
</tr>
<tr>
<td>IP_STATS_GetTxDiscardCnt()</td>
<td>Retrieves the number of packets to send but discarded although they were O.K.</td>
</tr>
<tr>
<td>IP_STATS_GetTxErrCnt()</td>
<td>Retrieves the number of send errors on an interface.</td>
</tr>
<tr>
<td>IP_STATS_GetTxNotUnicastCnt()</td>
<td>Retrieves the number of packets sent on an interface that were not unicasts.</td>
</tr>
<tr>
<td>IP_STATS_GetTxUnicastCnt()</td>
<td>Retrieves the number of unicast packets sent on an interface.</td>
</tr>
</tbody>
</table>

**Other IP stack functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_AddAfterInitHook()</td>
<td>Adds a hook to a callback that is executed at the end of IP_Init() to allow adding initializations to be executed right after the stack itself has been initialized and all API can be used.</td>
</tr>
<tr>
<td>IP_AddEtherTypeHook()</td>
<td>This function registers a callback to be called for received packets with the registered Ethernet type.</td>
</tr>
<tr>
<td>IP_AddLinkChangeHook()</td>
<td>Adds a callback that gets executed each time the link state changes.</td>
</tr>
<tr>
<td>IP_AddOnPacketFreeHook()</td>
<td>This function adds a hook function to the IP_HOOK_ON_PACKET_FREE list.</td>
</tr>
<tr>
<td>IP_AddStateChangeHook()</td>
<td>Adds a hook to a callback that is executed when the AdminState or HWState of an interface changes.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_Alloc()</td>
<td>Thread safe memory allocation from main IP stack memory pool.</td>
</tr>
<tr>
<td>IP_AllocEtherPacket()</td>
<td>Allocates a packet to store the raw data of an Ethernet packet of up to NumBytes at the location returned by ppBuffer.</td>
</tr>
<tr>
<td>IP_AllocEx()</td>
<td>Thread safe memory allocation from a specific memory pool managed by the stack that has been added using IP_AddMemory().</td>
</tr>
<tr>
<td>IP_ARP_CleanCache()</td>
<td>Cleans all ARP entries that are not static entries.</td>
</tr>
<tr>
<td>IP_ARP_CleanCacheByInterface()</td>
<td>Cleans all ARP entries that are known to belong to a specific interface and are not static entries.</td>
</tr>
<tr>
<td>IP_Connect()</td>
<td>Calls a previously registered hook for the interface if any was set using IP_SetIFaceConnectHook().</td>
</tr>
<tr>
<td>IP_Disconnect()</td>
<td>Calls a previously registered hook for the interface if any was set using IP_SetIFaceDisconnectHook().</td>
</tr>
<tr>
<td>IP_Err2Str()</td>
<td>Converts IP stack error code to a readable string by simply using the defines name.</td>
</tr>
<tr>
<td>IP_FindIFaceByIP()</td>
<td>Tries to find out the interface number when only the IP address is known.</td>
</tr>
<tr>
<td>IP_Free()</td>
<td>Thread safe memory free to IP stack memory pools.</td>
</tr>
<tr>
<td>IP_FreePacket()</td>
<td>Frees a packet back to the stack.</td>
</tr>
<tr>
<td>IP_GetAddrMask()</td>
<td>Retrieves the IP address and subnet mask of an interface.</td>
</tr>
<tr>
<td>IP_GetCurrentLinkSpeed()</td>
<td>Returns the current link speed of the first interface (interface ID 0).</td>
</tr>
<tr>
<td>IP_GetCurrentLinkSpeedEx()</td>
<td>Returns the current link speed of the requested interface.</td>
</tr>
<tr>
<td>IP_GetFreePacketCnt()</td>
<td>Checks how many packets for a specific size or greater are currently available in the system.</td>
</tr>
<tr>
<td>IP_GetIFaceHeaderSize()</td>
<td>Retrieves the size of the header necessary for the transport medium that is used by a specific interface.</td>
</tr>
<tr>
<td>IP_GetGWAddr()</td>
<td>Returns the gateway address of the interface in host endianess.</td>
</tr>
<tr>
<td>IP_GetHWAddr()</td>
<td>Returns the hardware address (Media Access Control address) of the interface.</td>
</tr>
<tr>
<td>IP_GetIPAddr()</td>
<td>Returns the IP address of the interface in host endianess.</td>
</tr>
<tr>
<td>IP_Get IPPacketInfo()</td>
<td>Returns the start address of the data part of an IP_PACKET.</td>
</tr>
<tr>
<td>IP_GetRawPacketInfo()</td>
<td>Returns the start address of the raw data of an IP_PACKET.</td>
</tr>
<tr>
<td>IP_GetVersion()</td>
<td>Returns the version of the stack.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>IP_ICMP_SetRxHook()</td>
<td>Sets a hook function which will be called if target receives a ping packet.</td>
</tr>
<tr>
<td>IP_IFaceIsReady()</td>
<td>Checks if the interface is ready for usage.</td>
</tr>
<tr>
<td>IP_IFaceIsReadyEx()</td>
<td>Checks if the specified interface is ready for usage.</td>
</tr>
<tr>
<td>IP_IsAllZero()</td>
<td>Checks if there are zeros at the given pointer.</td>
</tr>
<tr>
<td>IP_IsExpired()</td>
<td>Checks if the given system timestamp has already expired.</td>
</tr>
<tr>
<td>IP_NI_ConfigLinkCheckMultiplier()</td>
<td>Configures the multiplier of the period between interface link checks typically executed each second.</td>
</tr>
<tr>
<td>IP_NI_GetAdminState()</td>
<td>Retrieves the admin state of the given interface.</td>
</tr>
<tr>
<td>IP_NI_GetIFaceType()</td>
<td>Retrieves a short textual description of the interface type.</td>
</tr>
<tr>
<td>IP_NI_GetState()</td>
<td>Returns the hardware state of the interface.</td>
</tr>
<tr>
<td>IP_NI_SetAdminState()</td>
<td>Sets the AdminState of the interface.</td>
</tr>
<tr>
<td>IP_NI_GetTxQueueLen()</td>
<td>Retrieves the current length of the Tx queue of an interface.</td>
</tr>
<tr>
<td>IP_NI_PauseRxInt()</td>
<td>Pauses the Rx interrupt of an interface by disabling it temporary.</td>
</tr>
<tr>
<td>IP_PrintIPAddr()</td>
<td>Convert a 4-byte IP address to a dots-and-number string.</td>
</tr>
<tr>
<td>IPResolveHost()</td>
<td>Resolve a host name string to its IP address by using a configured DNS server.</td>
</tr>
<tr>
<td>IP_SendEtherPacket()</td>
<td>Sends a previously allocated Ethernet packet.</td>
</tr>
<tr>
<td>IP_SendPacket()</td>
<td>Sends a user defined packet on the interface.</td>
</tr>
<tr>
<td>IP_SendPing()</td>
<td>Sends a single ICMP echo request (&quot;ping&quot;) to the specified host.</td>
</tr>
<tr>
<td>IP_SendPingCheckReply()</td>
<td>Sends a single ICMP echo request (&quot;ping&quot;) to the specified host using the selected interface and waits for the reply.</td>
</tr>
<tr>
<td>IP_SendPingEx()</td>
<td>Sends a single ICMP echo request (&quot;ping&quot;) to the specified host using the selected interface.</td>
</tr>
<tr>
<td>IP_SetIFaceConnectHook()</td>
<td>Sets a hook for an interface that is executed when IP_Connect() is called.</td>
</tr>
<tr>
<td>IP_SetIFaceDisconnectHook()</td>
<td>Sets a hook for an interface that is executed when IP_Disconnect() is called.</td>
</tr>
<tr>
<td>IP_SetOnPacketFreeCallback()</td>
<td>This function sets a callback to be executed once the packet has been freed.</td>
</tr>
<tr>
<td>IP_SetPacketToS()</td>
<td>Sets the value of the ToS byte in the IP header of a packet to be sent via the zero-copy API.</td>
</tr>
<tr>
<td>IP_SetRxHook()</td>
<td>Sets a hook function which will be called if target receives a packet.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_SetMicrosecondsCallback()</td>
<td>Sets a callback that is used to get a timestamp in microseconds.</td>
</tr>
<tr>
<td>IP_SetRandCallback()</td>
<td>Sets a callback that can provide random data.</td>
</tr>
</tbody>
</table>
4.2 Configuration functions
4.2.1 IP_AddBuffers()

Description
Adds buffers to the TCP/IP stack. This is a configuration function, typically called from IP_X_Config(). It needs to be called 2 times, one per buffer size.

Prototype

```c
void IP_AddBuffers(int NumBuffers,
                   int BytesPerBuffer);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBuffers</td>
<td>The number of buffers.</td>
</tr>
<tr>
<td>BytesPerBuffer</td>
<td>Size of buffers in bytes.</td>
</tr>
</tbody>
</table>

Additional information
embOS/IP requires small and large buffers. We recommend to define the size of the big buffers to 1536 to allow a full Ethernet packet to fit. The small buffers are used to store packets which encapsulates no or few application data like protocol management packets (TCP SYNs, TCP ACKs, etc.). We recommend to define the size of the small buffers to 256 bytes.

Example

```c
IP_AddBuffers(20, 256); // 20 small buffers, each 256 bytes.
IP_AddBuffers(12, 1536); // 12 big buffers, each 1536 bytes.
```
4.2.2 IP_AddEtherInterface()

Description

Adds an Ethernet interface to the stack.

Prototype

```c
int IP_AddEtherInterface(const IP_HW_DRIVER * pDriver);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDriver</td>
<td>Pointer to a network interface driver structure.</td>
</tr>
</tbody>
</table>

Return value

Zero-based interface index of the newly created interface.

Additional information

While the order in which interfaces are added to the stack does not matter to the stack itself, it might be important for the driver to add.

Typically drivers for CPU integrated controllers are expected to be added first. Next drivers for external controllers can be added. As external controllers can be used as an extension to internal controllers they do not rely on a specific interface order.

To fill in gaps in the order of interfaces added, a dummy driver IP_Driver_Dummy can be added. A sample of such a configuration would be an application that relies on the following order: - IFace0: Internal controller - IFace1: External WiFi module The same hardware might be produced with a different configuration like only providing WiFi but using a cheaper CPU without internal controller. In this case the dummy driver can be used to keep up the same order: - IFace0: Dummy - IFace1: External WiFi module

For drivers and hardware that supports dual Ethernet the requirement to add drivers for internal controllers remain. For using both internal controllers this means: - IFace0: First internal controller - IFace1: Second internal controller - IFace2: External WiFi module When using only the second internal controller the interface index needs to be pushed by using the dummy driver again: - IFace0: Dummy - IFace1: Second internal controller - IFace2: External WiFi module However for using only the first controller of a driver that supports a dual unit, no dummy needs to be added before adding additional external drivers: - IFace0: First internal controller, second is not used. - IFace1: External WiFi module

Additional information

Refer to *Available network interface drivers* on page 491 for a list of available network interface drivers.

Example

```c
IP_AddEtherInterface(&IP_Driver_SAM7X); // Add Ethernet driver for your hardware
```
4.2.3 IP_AddVirtEtherInterface()

Description
Adds a virtual interface to the stack that uses a hardware interface for communication.

Prototype

```c
int IP_AddVirtEtherInterface(unsigned HWIFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HWIFaceId</td>
<td>Zero-based interface index of the hardware interface.</td>
</tr>
</tbody>
</table>

Return value

Zero-based interface index of the newly created interface.

Additional information

Virtual interfaces can be added to allow configuration of multiple IP addresses on the same target. One configuration can be assigned per interface.

Example

```c
int IFaceId;

IFaceId = IP_AddEtherInterface(&IP_Driver_SAM7X);    // Add HW Ethernet driver
IP_AddVirtEtherInterface(IFaceId);
```
### 4.2.4 IP_AddLoopbackInterface()

**Description**
Adds a loopback interface to the stack.

**Prototype**

```c
int IP_AddLoopbackInterface(void);
```

**Return value**
Zero-based interface index of the newly created interface.

**Additional information**
The loopback interface will be added with the pre-configured static IP address of 127.0.0.1/8.

**Example**

```c
IP_AddLoopbackInterface(); // Add an Ethernet loopback interface.
```
4.2.5 IP_AddMemory()

Description
This function is called from the application to add additional memory to the stack. IP_AssignMemory() needs to be called first.

Prototype

```c
void IP_AddMemory(U32 * pMem,
                   U32   NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pMem</td>
<td>A pointer to the start of the memory region which should be added.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes which should be added.</td>
</tr>
</tbody>
</table>

Additional information
This function can be used to add additional memory to the stack that can then be requested by application level modules such as Web server or FTP server directly from the stacks memory management.

For further information about the available memory management functions, refer to IP_Alloc on page 202 and IP_Free on page 211.

Example

```c
#define MEM_SIZE  0x8000   // Size of memory to add to the stack in bytes.
U32  _aMem [MEM_SIZE / 4];   // Memory area to add to the stack.

IP_AddMemory(_aMem, sizeof(_aMem));
```
4.2.6 IP_AllowBackPressure()

Description
Allows back pressure if the driver supports this feature.

Prototype

```c
void IP_AllowBackPressure(char v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>v</code></td>
<td>0 to disable, 1 to enable back pressure.</td>
</tr>
</tbody>
</table>
4.2.7 IP_AssignMemory()

Description
Assigns memory to the stack.

Prototype

```c
void IP_AssignMemory(U32 * pMem,
                   U32   NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pMem</td>
<td>A pointer to the start of the memory region which should be assigned.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes which should be assigned.</td>
</tr>
</tbody>
</table>

Additional information

IP_AssignMemory() should be the first function which is called in IP_X_Config(). The amount of RAM required depends on the configuration and the respective application purpose. The assigned memory pool is required for the socket buffers, memory buffers, etc.

Example

```c
#define ALLOC_SIZE   0x8000
   // Size of memory dedicated to the stack in bytes
U32 _aPool[ALLOC_SIZE / 4];   // Memory area used by the stack.

IP_AssignMemory(_aPool, sizeof(_aPool));
```
4.2.8  IP_ARP_ConfigAgeout()

Description

Configures the timeout for cached ARP entries. The ARP timer removes entries which have not been used for a time longer than AgeOut.

Prototype

void IP_ARP_ConfigAgeout(U32 Ageout);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ageout</td>
<td>Timeout in ms after which an entry is deleted from the ARP cache. Default: 30s.</td>
</tr>
</tbody>
</table>
4.2.9  IP_ARP_ConfigAgeoutNoReply()

Description
Configures the timeout for an ARP entry that has been added due to sending an ARP request
to the network that has not been answered yet.

Prototype

```c
void IP_ARP_ConfigAgeoutNoReply(U32 Ageout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ageout</td>
<td>Timeout in ms after which an entry is deleted in case we are still waiting for an ARP response. Default: 3s.</td>
</tr>
</tbody>
</table>
4.2.10 IP_ARP_ConfigAgeoutSniff()

Description

Configures the age out value for ARP entries, which we have created by looking up addresses of received IP packets. The ARP timer removes entries which have not been used for a time longer than AgeOut.

Prototype

```c
void IP_ARP_ConfigAgeoutSniff(U32 Ageout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ageout</td>
<td>Timeout in ms after which an entry is deleted from the ARP cache. Default: 500ms.</td>
</tr>
</tbody>
</table>
4.2.11  IP_ARP_ConfigAllowGratuitousARP()

Description

Configures if gratuitous ARP packets from other network members are allowed to update the ARP cache.

Prototype

```c
void IP_ARP_ConfigAllowGratuitousARP(U8 OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnOff</td>
<td>Default: On.</td>
</tr>
<tr>
<td></td>
<td>• 0: Off.</td>
</tr>
<tr>
<td></td>
<td>• 1: On.</td>
</tr>
</tbody>
</table>

Additional information

Gratuitous ARP packets allow the network to update itself by sending out informations about changes regarding IP and hardware ID assignments. As this behaviour helps the network to become more stable and helps to manage itself it is on by default.

In case you consider gratuitous ARP packets as a security risk IP_ARP_ConfigAllowGratuitousARP() can be used to disallow this behaviour.
4.2.12   IP_ARP_ConfigMaxPending()

Description
Configures the maximum number packets that can be queued waiting for an ARP reply.

Prototype

    void IP_ARP_ConfigMaxPending(unsigned NumPackets);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumPackets</td>
<td>Maximum number of packets that can be pending for one ARP entry. Default: 3.</td>
</tr>
</tbody>
</table>
4.2.13  IP_ARP_ConfigMaxRetries()

Description
Configures how often an ARP request is resent before considering the request failed.

Prototype

```c
void IP_ARP_ConfigMaxRetries(unsigned Retries);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retries</td>
<td>Number of retries for sending an ARP request. Default: 8.</td>
</tr>
</tbody>
</table>
4.2.14 IP_ARP_ConfigNumEntries()

Description
Configures the maximum number of possible entries in the ARP cache.

Prototype

```
int IP_ARP_ConfigNumEntries(unsigned NumEntries);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumEntries</td>
<td>New value to use as number of entries. Default: 8.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK, stack will try to allocate the requested number of ARP entries.</td>
</tr>
<tr>
<td>-1</td>
<td>Error, called after IP_Init().</td>
</tr>
</tbody>
</table>

Additional information

The function must be called before the initialization of the stack has been finished. We recommend to call it in IP_X_Config().
4.2.15  IP_BSP_SetAPI()

Description
Sets an API to be used for BSP related abstraction like initializing hardware and installing interrupt handlers.

Prototype

```c
void IP_BSP_SetAPI( unsigned IFaceId,
                     const BSP_IP_API * pAPI );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pAPI</td>
<td>Pointer to function table to use. For further information regarding <code>BSP_IP_API</code> please refer to Structure <code>BSP_IP_API</code>.</td>
</tr>
</tbody>
</table>
4.2.16 IP_ConfigMaxIFaces()

Description
Configures the maximum number of interfaces that can be added to the system.

Prototype

```c
void IP_ConfigMaxIFaces(unsigned NumIFaces);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumIFaces</td>
<td>Number of interfaces to allocate memory for.</td>
</tr>
</tbody>
</table>

Additional information

The memory for the driver list will be pre-allocated for the maximum allowed number of interfaces. The system uses the default value of `IP_MAX_IFACES` if not configured else with this function. To save some memory the maximum number of interfaces should be only the number of interfaces that are really required.
4.2.17  IP_ConfigNumLinkDownProbes()

Description

Configures the number of continuous link down probes to take before the stack accepts the link down status.

Prototype

```c
void IP_ConfigNumLinkDownProbes(U8 IFaceId,
                                 U8 NumProbes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>NumProbes</td>
<td>Number of continuous link down probes to take before link down is set in the stack.</td>
</tr>
</tbody>
</table>

Additional information

On unstable hardware or unstable network hardware like a switch a link jitter might occur. This jitter might lead to disconnects on upper protocol layers like TCP that might be disconnected once a link down is recognized. To prevent this to happen due to link jitter, multiple samples of a link down state can be taken before actually accepting the link down.

Typically the link status is checked once per second. Therefore by default `NumProbes = seconds after which the link state in the stack is allowed to really get down after the first link down reported by the driver. This routine is only effective in case the define `IP_NUM_LINK_DOWN_PROBES` is not 0.
**4.2.18 IP_ConfigNumLinkUpProbes()**

*Description*

Configures the number of continuous link up probes to take before the stack accepts the link up status.

*Prototype*

```c
void IP_ConfigNumLinkUpProbes(U8 IFaceId, U8 NumProbes);
```

*Parameters*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>NumProbes</td>
<td>Number of continuous link up probes to take before link up is set in the stack.</td>
</tr>
</tbody>
</table>

*Additional information*

Some switches might already report a link between switch and target but are not immediately operational resulting in packets getting lost until fully operational.

Typically the link status is checked once per second. Therefore by default `NumProbes = seconds after which the link state in the stack is allowed to really get up after the first link up reported by the driver.`

At the moment this only applies to Ethernet interfaces to address this behavior with some Ethernet switches.

This routine is only effective in case the define `IP_NUM_LINK_UP_PROBES` is not 0.
4.2.19    IP_ConfigOffCached2Uncached()

Description
Configures the offset from a cached memory area to its uncached equivalent for uncached access.

Prototype

```c
void IP_ConfigOffCached2Uncached(I32 Off);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Off</td>
<td>Offset from cached to uncached area. Can be negative if uncached area is before cached area.</td>
</tr>
</tbody>
</table>

Additional information
This function needs to be called in case the microcontroller is utilizing cache. Typically the data area that is used by default is accessed cached. In this case the stack needs to know where it can bypass the cache to write hardware related data such as driver descriptors that will be accessed by a DMA.
4.2.20 IP_ConfigTCPSpace()

Description
Configures the size of the TCP send and receive window size.

Prototype

```c
void IP_ConfigTCPSpace(unsigned SendSpace,
            unsigned RecvSpace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SendSpace</td>
<td>Transmit window size.</td>
</tr>
<tr>
<td>RecvSpace</td>
<td>Receive window size.</td>
</tr>
</tbody>
</table>

Additional information

The receive window size is the amount of unacknowledged data a sender can send to the receiver on a particular TCP connection before it gets an acknowledgment.
4.2.21  IP_DisableIPRxChecksum()

Description
Disables checksum verification of the checksum in the IP header for incoming packets.

Prototype

```c
void IP_DisableIPRxChecksum(U8 IFace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information
In a typical network all data contained in a transferred frame have already been verified by the hardware checking the transmitted frames checksum and it is unlikely that data within this frame are corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.2.22  IP_DisableIPv4()

Description
Disables IPv4 in the stack as good as possible.

Prototype

```c
void IP_DisableIPv4(void);
```

Additional information

Needs to be called before `IP_Init()` or during `IP_X_Config()`. As IPv4 is a base component of the stack, disabling IPv4 will be done to the best as possible. Also disables other IPv4 related protocols like ARP and ICMPv4.
4.2.23 IP_CACHE_SetConfig()

Description
Configures cache related functionality that might be required by the stack for several purposes such as cache handling in drivers.

Prototype

```
void IP_CACHE_SetConfig(const SEGGER_CACHE_CONFIG * pConfig,
                        unsigned ConfSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pConfig</td>
<td>Pointer to an element of SEGGER_CACHE_CONFIG.</td>
</tr>
<tr>
<td>ConfSize</td>
<td>Size of the passed structure in case library and header size of the structure differs.</td>
</tr>
</tbody>
</table>

Additional information

IP_CACHE_SetConfig() has to be called before IP_Init() or during IP_X_Config(). Typically used together with IP_ConfigOffCached2Uncached().
4.2.24  IP_DNS_GetServer()

Description
Retrieves the first DNS server configured of the first interface.

Prototype
U32 IP_DNS_GetServer(void);

Return value
IP address of the DNS server in network-byte-order.
4.2.25   IP_DNS_GetServerEx()

Description
Retrieves a DNS server configured for an interface.

Prototype

```c
void IP_DNS_GetServerEx(unsigned IFaceId,
                         U8 DNSIndex,
                         U8 * pAddr,
                         int * pAddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>DNSIndex</td>
<td>Zero-based index of the server to retrieve from interface.</td>
</tr>
<tr>
<td>pAddr</td>
<td>Pointer to a U32 variable to store the IPv4 DNS address.</td>
</tr>
<tr>
<td>pAddrLen</td>
<td>Length of DNS addr. in bytes. Typically 4 for IPv4.</td>
</tr>
</tbody>
</table>
4.2.26 IP_DNS.ResolveHostEx()

Description
Sends a query to the DNS server. The function blocks until the reply is received or for a maximum time.

Prototype

```c
int IP_DNS_ResolveHostEx( unsigned IFaceId,
                            const IP_DNSSD_REQUEST * pRequest,
                            int ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pRequest</td>
<td>Pointer on the request description.</td>
</tr>
<tr>
<td>ms</td>
<td>Maximum time to wait for a reply (around 5s for all attempts).</td>
</tr>
</tbody>
</table>

Return value

- = 0 Request is valid.
- = 1 No reply. All attempts not done.
- < 0 No reply all attempts done or request invalid.
4.2.27  IP_DNS_SendDynUpdate()

Description

Build a dynamic update request. It could send the IPv4 address and/or a request to clear all previous records.

Prototype

```c
int IP_DNS_SendDynUpdate( unsigned IFaceId,
const char * sHost,
const char * sDomain,
U32 IPv4Addr,
int ClearPreviousRR,
U32 ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Index of the interface.</td>
</tr>
<tr>
<td>sHost</td>
<td>Null-terminated string of the host to update.</td>
</tr>
<tr>
<td>sDomain</td>
<td>Null-terminated string of the domain name.</td>
</tr>
<tr>
<td>IPv4Addr</td>
<td>IPv4 address used for the update. Set to 0 to ignore.</td>
</tr>
<tr>
<td>ClearPreviousRR</td>
<td>Sent an update request to remove all previous records.</td>
</tr>
<tr>
<td>ms</td>
<td>Time in ms that the function is waiting for a reply. The reply might still be fulfilled after the timeout.</td>
</tr>
</tbody>
</table>

Return value

= 1    Send is pending
= 0    Success
< 0    Error
4.2.28  IP_DNS_SetTSIGContext()

Description
Set the TSIG signature context with the parameters needed to perform Secured Dynamic Updates signed with TSIG.

Prototype

```c
void IP_DNS_SetTSIGContext
('#' char * KeyName,
'char * KeyAlgoName,
'int (*pfSign)
(U8 * pData, U16 DataLength, U8 * pDigest, int DigestMaxSize),
'int (*pfGetTime)(U32 * pSeconds));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KeyName</td>
<td>Pointer to the string containing the key name. Only the pointer is kept so the string must be static.</td>
</tr>
<tr>
<td>KeyAlgoName</td>
<td>Pointer to the string containing the algorithm name. Only the pointer is kept so the string must be static.</td>
</tr>
<tr>
<td>pfSign</td>
<td>Function pointer on the function which is called to do the crypto signature.</td>
</tr>
<tr>
<td>pfGetTime</td>
<td>Function pointer on the function used to get the current time in seconds since 1th January 1970.</td>
</tr>
</tbody>
</table>
4.2.29   IP_DNS_SetMaxTTL()

Description
Sets the maximum Time To Live (TTL) of a DNS entry in seconds.

Prototype

```c
void IP_DNS_SetMaxTTL(U32 TTL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTL</td>
<td>Maximum TTL of a DNS entry in seconds.</td>
</tr>
</tbody>
</table>

Additional information

The real TTL is the minimum of this value and the TTL specified by the DNS server for the entry. The embOS/IP default for the maximum TTL of an DNS entry is 600 seconds.
4.2.30 IP_DNS_SetServer()

Description
Sets the DNS server address of the first interface.

Prototype

```c
void IP_DNS_SetServer(U32 DNSServerAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNSServerAddr</td>
<td>IP address of the DNS server.</td>
</tr>
</tbody>
</table>

Additional information

If a DHCP server is used for configuring your target, IP_DNS_SetServer() should not be called. The DNS server settings are normally part of the DHCP configuration setup. The DNS server has to be defined before calling gethostbyname() to resolve an internet address.
4.2.31 IP_DNS_SetServerEx()

Description
Sets the IP address of the available DNS servers for an interface.

Prototype

```c
int IP_DNS_SetServerEx( unsigned IFaceId, U8 DNSIndex, const U8 * pDNSAddr, int AddrLen );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>DNSIndex</td>
<td>Zero-based index of DNS servers.</td>
</tr>
<tr>
<td>pDNSAddr</td>
<td>Pointer to memory location holding the DNS addresse to set. Typically an 4-byte IP addresse.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>Length of IP addresse of server. Typically 4-bytes.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK.</td>
</tr>
<tr>
<td>1</td>
<td>Error.</td>
</tr>
</tbody>
</table>
4.2.32 IP_MDNS.ResolveHost()

Description
Sends a query using Multicast DNS. The function blocks until the reply is received or for a maximum time.

Prototype

```c
int IP_MDNSResolveHost(unsigned IFaceId, const IP_DNSSD_REQUEST * pRequest, int ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pRequest</td>
<td>Pointer on the request description.</td>
</tr>
<tr>
<td>ms</td>
<td>Maximum time to wait for a reply (around 5s for all attempts).</td>
</tr>
</tbody>
</table>

Return value

- 0  Request is valid.
- 1  No reply. All attempts not done.
- < 0 No reply all attempts done or request invalid.

Additional information

When the requested type is A (IPv4 address) or AAAA (IPv6 address), the request is sent for both Apple mDNS and Microsoft LLMNR. Other DNS-SD request are sent only on mDNS.
4.2.33  IP_EnableIPRxChecksum()

Description
Enables the IP Rx checksum calculation in the IP header for incoming packets. This is the default behaviour of the stack.

Prototype

```c
void IP_EnableIPRxChecksum(U8 IFace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information
In a typical network all data contained in a transferred frame have already been verified by the hardware checking the transmitted frames checksum and it is unlikely that data within this frame are corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.2.34 IP_GetMaxAvailPacketSize()

**Description**

Asks the stack for the maximum available free packet size that can then be allocated. (e.g. with a zero-copy alloc).

**Prototype**

```c
U32 IP_GetMaxAvailPacketSize(int IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index for which the packet shall be allocated.</td>
</tr>
</tbody>
</table>

**Return value**

No free packet is available at all: 0. Other: Max. packet size that is free.

**Additional information**

The packet size returned does not contain any protocol headers other than the transport layer (for Ethernet typically 14 bytes/for PPP typically 6 bytes). Other protocol header such as IPvX and UDPvX need to be subtracted from the value returned.
4.2.35  IP_GetMTU()

Description
Retrieves the configured TCP MTU size for an interface.

Prototype

U32 IP_GetMTU(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
MTU configured for the interface, either set as default when adding the interface or set via IP_SetMTU().
4.2.36  IP_GetPrimaryIFace()

Description
Retrieves the currently set primary interface index.

Prototype

```c
int IP_GetPrimaryIFace(void);
```

Return value
Currently set primary interface index. Default is 0.
4.2.37 IP_ICMP_Add()

Description
Adds ICMP Protocol function to the stack.

Prototype

void IP_ICMP_Add(void);

Additional information

IP_ICMP_Add() adds ICMP to the stack. The function should be called during the initialization of the stack. In the supplied sample configuration files IP_ICMP_Add() is called from IP_X_Config(). If you remove the call of IP_ICMP_Add(), the ICMP code will not be available in your application.
4.2.38 IP_ICMP_DisableRxChecksum()

Description
Disables the ICMP Rx checksum calculation. The ICMP checksum computation can be disabled to improve the performance of the stack.

Prototype

```c
void IP_ICMP_DisableRxChecksum(U8 IFace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Interface index.</td>
</tr>
</tbody>
</table>

Additional information

In a typical network all data contained in a transferred frame have already been verified by the hardware by checking the transmitted frames checksum. It is unlikely that data within this frame is corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.2.39  IP_ICMP_EnableRxChecksum()

Description
Enables the ICMP Rx checksum calculation. This is the default behaviour of the stack. The ICMP checksum computation can be disabled to improve the performance of the stack.

Prototype

```c
void IP_ICMP_EnableRxChecksum(U8 IFace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information

In a typical network all data contained in a transferred frame have already been verified by the hardware by checking the transmitted frames checksum. It is unlikely that data within this frame is corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.2.40  **IP_IGMP_Add()**

**Description**

Adds IGMP Protocol function to stack for interface 0.

**Prototype**

```c
int IP_IGMP_Add(void);
```

**Return value**

- = 0  Success.
- ≠ 0  Error.

**Additional information**

`IP_IGMP_Add()` adds IGMP (Internet Group Management Protocol) to the stack. The function should be either called during the initialization of the stack by adding it to your `IP_X_Config()` or should be called after `IP_Init()`. If you remove the call of `IP_IGMP_Add()`, the IGMP code will not be available in your application.
4.2.41  IP_IGMP_AddEx()

Description
Adds IGMP Protocol function to the stack for a specified interface.

Prototype

```c
int IP_IGMP_AddEx(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

- = 0  Success.
- ≠ 0 Error.

Additional information

IP_IGMP_Add() adds IGMP (Internet Group Management Protocol) to the stack. The function should be either called during the initialization of the stack by adding it to your IP_X_Config() or should be called after IP_Init(). If you remove the call of IP_IGMP_Add(), the IGMP code will not be available in your application.
4.2.42 IP_IGMP_JoinGroup()

Description

Joins an IGMP group.

Prototype

```c
void IP_IGMP_JoinGroup ( unsigned IFaceId,
                        IP_ADDR GroupIP );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index to register with the IGMP group.</td>
</tr>
<tr>
<td>GroupIP</td>
<td>IGMP group IP addresse to join.</td>
</tr>
</tbody>
</table>

Additional information

Calling this function should be only done after IP_init() as we relay on an already configured HW addr.

Multicast is a technique to distribute a packet to multiple receivers in a network by sending only one packet. Handling of who will receive the packet is not done by the sender but instead is done by network hardware such as routers or switched hubs that will duplicate the packet and send it to everyone that participates the chosen group.

The target does not actively participate by sending a join request. The network hardware periodically broadcasts membership queries throughout the network that have to be answered with a membership report in case we want to participate in the queried group.

Example

```c
/* Excerpt from IP.h */
#define IP_IGMP_MCAST_ALLHOSTS_GROUP  0xE0000001uL // 224.0.0.1
#define IP_IGMP_MCAST_ALLRPTS_GROUP   0xE0000016uL // 224.0.0.22, IGMPv3

/* Excerpt from the UPnP code */
#define SSDP_IP  0xEFFFFFFA // Simple service discovery prot. IP, 239.255.255.250

IP_IGMP_Add(); // IGMP is needed for UPnP

// Join IGMP ALLHOSTS group and IGMP group for SSDP
IP_IGMP_JoinGroup(0, IP_IGMP_MCAST_ALLHOSTS_GROUP);
IP_IGMP_JoinGroup(0, SSDP_IP);
```
4.2.43  IP_IGMP_LeaveGroup()

Description
Leaves an IGMP group.

Prototype

```c
void IP_IGMP_LeaveGroup(unsigned IFaceId, IP_ADDR GroupIP);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index registered with the IGMP group</td>
</tr>
<tr>
<td>GroupIP</td>
<td>IGMP group IP addresse to leave.</td>
</tr>
</tbody>
</table>

Additional information

The target does not actively participate by sending a leave request. Instead the target will change its filters to no longer receiving IGMP membership queries and will then be removed from the list of participants of the network hardware after a timeout.

Example

```c
/* Excerpt from IP.h */
#define IP_IGMP_MCAST_ALLHOSTS_GROUP 0xE0000001uL  // 224.0.0.1
#define IP_IGMP_MCAST_ALLRPTS_GROUP   0xE0000016uL // 224.0.0.22, IGMPv3

/* Excerpt from the UPnP code */
#define SSDP_IP  0xEFFFFFFA // Simple service discovery prot. IP, 239.255.255.250

//
// Leave IGMP ALLHOSTS group and IGMP group for SSDP
//
IP_IGMP_LeaveGroup(0, IP_IGMP_MCAST_ALLHOSTS_GROUP);
IP_IGMP_LeaveGroup(0, SSDP_IP);
```
4.2.44  IP_RAW_Add()

Description
Adds RAW socket function to stack

Prototype

\texttt{void IP_RAW_Add(void);} 

Additional information
\texttt{IP_RAW_Add()} adds RAW socket support to the stack. The function should be called during the initialization of the stack.
4.2.45  IP_SetAddrMask()

Description
Sets the IP address and subnet mask of an interface. Operates on interface 0.

Prototype

void IP_SetAddrMask(U32 Addr,
                    U32 Mask);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Addr</td>
<td>IP address in host endianess.</td>
</tr>
<tr>
<td>Mask</td>
<td>Subnet mask in host endianess.</td>
</tr>
</tbody>
</table>

Additional information
The address mask should only be set if no DHCP server is used to obtain IP address, subnet mask and default gateway.

Refer to chapter DHCP client on page 349 for detailed information about the usage of the embOS/IP DHCP client.

Example

IP_SetAddrMask(0xC0A80505, 0xFFFF0000);  // IP: 192.168.5.5
                                            // Subnet mask: 255.255.0.0
4.2.46   IP_SetAddrMaskEx()

Description
Sets the IP address and subnet mask of an interface.

Prototype

```c
void IP_SetAddrMaskEx ( U8 IFace,
                      U32 Addr,
                      U32 Mask );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Interface number.</td>
</tr>
<tr>
<td>Addr</td>
<td>IP address in host endianess.</td>
</tr>
<tr>
<td>Mask</td>
<td>Subnet mask in host endianess.</td>
</tr>
</tbody>
</table>

Additional information
The address mask should only be set if no DHCP server is used to obtain IP address, subnet mask and default gateway.

Refer to chapter **DHCP client** on page 349 for detailed information about the usage of the embOS/IP DHCP client.

Example

```c
IP_SetAddrMaskEx(0, 0xC0A80505, 0xFFFF0000); // IP: 192.168.5.5
// Subnet mask: 255.255.0.0
```
4.2.47  IP_SetGWAddr()

Description
Sets the default gateway address of the selected interface.

Prototype

```c
void IP_SetGWAddr(U8 IFace,
                  U32 GWAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>GWAddr</td>
<td>4-byte gateway address in host endianess.</td>
</tr>
</tbody>
</table>

Additional information

The address mask should only be set if no DHCP server is used to obtain IP address, subnet mask and default gateway.

Refer to chapter **DHCP client** on page 349 for detailed information about the usage of the embOS/IP DHCP client.

Example

```c
IP_SetGWAddr(0, 0x0A80101);  // Interface: 0
// IPv4 address of the GW: 192.168.1.1
```
4.2.48 IP_SetHWAddr()

Description
Sets the Media Access Control address (MAC) of the interface 0.

Prototype

```c
void IP_SetHWAddr(const U8 * pHWAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHWAddr</td>
<td>6 bytes MAC address.</td>
</tr>
</tbody>
</table>

Additional information

The MAC address needs to be unique for production units.

Example

```c
IP_SetHWAddr("\x00\x22\x33\x44\x55\x66");
```
### 4.2.49  IP_SetHWAddrEx()

**Description**
Sets the Media Access Control address (MAC) of the selected interface.

**Prototype**
```c
void IP_SetHWAddrEx(       unsigned    IFaceId ,
                          const  U8       *  pHWAddr ,
                          unsigned    NumBytes );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pHWAddr</td>
<td>Pointer on the MAC address.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes of the MAC address (typically 6).</td>
</tr>
</tbody>
</table>

**Additional information**
The MAC address needs to be unique for production units.

**Example**
```c
IP_SetHWAddrEx( 0 , "\x00\x22\x33\x44\x55\x66" , 6 );
```
4.2.50 IP_SetMTU()

Description
Allows to set the maximum transmission unit (MTU) of an interface.

Prototype

```c
void IP_SetMTU(unsigned IFaceId, U32 Mtu);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Mtu</td>
<td>Size of maximum transmission unit in bytes.</td>
</tr>
</tbody>
</table>

Additional information

The Maximum Transmission Unit is the MTU from an IP standpoint, so the size of the IP-packet without local net header. A typical value for ethernet is 1500, since the maximum size of an Ethernet packet is 1518 bytes. Since Ethernet uses 12 bytes for MAC addresses, 2 bytes for type and 4 bytes for CRC, 1500 bytes “payload” remain. The minimum size of the MTU is 576 according to RFC 879. Refer to [RFC 879] - TCP - The TCP Maximum Segment Size and Related Topics for more information about the MTU.

A smaller MTU size is effective for TCP connections only, it does not affect UDP connections. All TCP connections are guaranteed to work with any MTU in the permitted range of 576 - 1500 bytes. The advantage of a smaller MTU is that smaller packets are sent in TCP communication, resulting in reduced RAM requirements, especially if the window size is also reduced. The disadvantage is a loss of communication speed.

Note:
In the supplied embOS/IP example configurations, the MTU is used to configure the maximum packet size that the stack can handle. This means that if you lower the MTU (for example, set it to 576 bytes), the stack can only handle packets up to that size. If you plan to use larger UDP packets, change the configuration according to your requirements. For further information about the configuration of the stack, refer to Configuring embOS/IP on page 525.
4.2.51  IP_SetMicrosecondsCallback()

Description
Sets a callback that is used to get a timestamp in microseconds.

Prototype

```c
void IP_SetMicrosecondsCallback(U64 (*pfGetTime_us)());
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGetTime_us</td>
<td>The callback to set.</td>
</tr>
</tbody>
</table>
4.2.52 IP_SetRandCallback()

Description
Sets a callback that can provide random data.

Prototype

```c
void IP_SetRandCallback (void (*pfGetRand)(U8 * pBuffer, unsigned NumBytes ));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGetRand</td>
<td>Callback function that provides randomized data.</td>
</tr>
</tbody>
</table>

Example

```c
/**************************************************************************
* 
*   _cbRand()
* 
*   Function description
*   Provides a source of randomness.
* 
*   Parameters
*   pBuffer : Pointer where to store the random data.
*   NumBytes: Number of random bytes to store. 
*/
static void _cbRand (U8 * pBuffer, unsigned NumBytes) {
    //
    // Generate NumBytes of random data and store it at pBuffer.
    //
}

IP_SetRandCallback (_cbRand);
```
4.2.53  IP_SetPrimaryIFace()

Description
Sets the primary interface index.

Prototype

```c
int IP_SetPrimaryIFace(int IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index to use as primary interface of the system. Default is 0.</td>
</tr>
</tbody>
</table>

Return value

- = 0       OK.
- < 0       Error.

Additional information

The primary interface is given priority for several purposes in multi interface setups. One example would be to use a preferred interface when looking for a DNS server to use in case multiple interface have set DNS servers.
4.2.54  IP_SetSupportedDuplexModes()

Description
Allows to set the allowed duplex mode of the device.

Prototype

```c
int IP_SetSupportedDuplexModes(unsigned IFace,
                                 unsigned DuplexMode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>DuplexMode</td>
<td>OR combination of one or more of the following valid values.</td>
</tr>
</tbody>
</table>

Return value

- = 0   Success
- < 0   Not supported.

Valid values for parameter DuplexMode

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PHY_MODE_10_HALF</td>
<td>Support 10 Mbit half-duplex</td>
</tr>
<tr>
<td>IP_PHY_MODE_10_FULL</td>
<td>Support 10 Mbit full-duplex</td>
</tr>
<tr>
<td>IP_PHY_MODE_100_HALF</td>
<td>Support 100 Mbit half-duplex</td>
</tr>
<tr>
<td>IP_PHY_MODE_100_FULL</td>
<td>Support 100 Mbit full-duplex</td>
</tr>
<tr>
<td>IP_PHY_MODE_1000_HALF</td>
<td>Support 1000 Mbit half-duplex</td>
</tr>
<tr>
<td>IP_PHY_MODE_1000_FULL</td>
<td>Support 1000 Mbit full-duplex</td>
</tr>
</tbody>
</table>
4.2.55 IP_SetTTL()

Description
Sets the default value for the Time-To-Live IP header field.

Prototype

```c
void IP_SetTTL(int v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>Time-To-Live value.</td>
</tr>
</tbody>
</table>

Additional information

By default, the TTL (Time-To-Live) is 64. The TTL field length of the IP is 8 bits. The maximum value of the TTL field is therefore 255.
4.2.56  IP_SetGlobalMcTTL()

Description
Sets the default value for the Time-To-Live IP header field for global multicast packets.

Prototype

\[
\text{void IP\_SetGlobalMcTTL(int } v); 
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( v )</td>
<td>Time-To-Live value.</td>
</tr>
</tbody>
</table>

Additional information
By default, the TTL (Time-To-Live) is 64. The TTL field length of the IP is 8 bits. The maximum value of the TTL field is therefore 255.

Global multicast packets are packets with destinations outside the following networks:
- 224.0.0.x
- 239.x.x.x
4.2.57  IP_SetLocalMcTTL()

Description
Sets the default value for the Time-To-Live IP header field for local multicast packets.

Prototype

```c
void IP_SetLocalMcTTL(int v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>Time-To-Live value.</td>
</tr>
</tbody>
</table>

Additional information

By default, the TTL (Time-To-Live) is 64. The TTL field length of the IP is 8 bits. The maximum value of the TTL field is therefore 255.

Local multicast packets are packets with destinations inside the following networks:
- 224.0.0.x
- 239.x.x.x
4.2.58  IP_SOCKET_ConfigSelectMultiplicator()

Description
Configures the multiplicator for the timeout parameter of select(). Default multiplicator is 1.

Prototype

```
void IP_SOCKET_ConfigSelectMultiplicator(U32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>Multiplicator to be used.</td>
</tr>
</tbody>
</table>

Additional information
By default the select() timeout is given in ticks of 1 ms. The UNIX standard takes the timeout in a structure including seconds. The multiplicator can be configured but as it is more common for an embedded system we will stick to units of 1 tick (typically 1 ms) for the default.
4.2.59  IP_SOCKET_SetDefaultOptions()

Description
Sets the socket options enabled by default.

Prototype

```c
void IP_SOCKET_SetDefaultOptions(U16 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>Socket options which should be enabled.</td>
</tr>
</tbody>
</table>

Additional information

By default, keepalive (SO_KEEPALIVE) socket option is enabled. Refer to `setsockopt()` for a list of supported socket options.
4.2.60  IP_SOCKET_SetLimit()

Description
Sets the maximum number of allowed sockets.

Prototype

```c
void IP_SOCKET_SetLimit(unsigned Limit);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit</td>
<td>Sets a limit on number of sockets which can be created. The embOS/IP default is 0 which means that no limit is set.</td>
</tr>
</tbody>
</table>
4.2.61  IP_SYSVIEW_Init()

Description
Initializes the embOS/IP profile instrumentation and SystemView as profiling implementation.

Prototype

```c
void IP_SYSVIEW_Init(void);
```

Additional information
For further information regarding the SysView profiling implementation in embOS/IP please refer to the chapter *Profiling with SystemView* on page 1157.
4.2.62  IP_TCP_Add()

Description
Adds TCP Protocol function to the stack.

Prototype

```c
void IP_TCP_Add(void);
```

Additional information

IP_TCP_Add() adds TCP to the stack. The function should be called during the initialization of the stack. In the supplied sample configuration files IP_TCP_Add() is called from IP_X_Config(). If you remove the call of IP_TCP_Add(), the TCP code will not be available in your application.
4.2.63  IP_TCP_DisableRxChecksum()

Description
Disables the TCP Rx checksum calculation. The TCP checksum computation can be disabled
to improve the performance of the stack.

Prototype
void  IP_TCP_DisableRxChecksum(U8 IFace);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information
In a typical network all data contained in a transferred frame has already been verified by
the hardware checking the transmitted frames checksum and it is unlikely that data within
this frame is corrupted if the frame checksum was verified as being correct. Therefore for
optimization reasons the checksum calculation might be disabled.
4.2.64  IP_TCP_EnableRxChecksum()

Description
Enables checksum verification of the checksum in the TCP header for incoming packets.

Prototype

```c
void IP_TCP_EnableRxChecksum(U8 IFace);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information

In a typical network all data contained in a transferred frame has already been verified by the hardware checking the transmitted frames checksum and it is unlikely that data within this frame is corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
### 4.2.65 IP_TCP_Set2MSLDelay()

**Description**
Sets the maximum segment lifetime (MSL).

**Prototype**

```c
void IP_TCP_Set2MSLDelay(unsigned v);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>Maximum segment lifetime. The embOS/IP default is 2 seconds.</td>
</tr>
</tbody>
</table>

**Additional information**

The maximum segment lifetime is the amount of time any segment can exist in the network before being discarded. This time limit is constricted. When TCP performs an active close the connection must stay in `TIME_WAIT` (2MSL) state for twice the MSL after sending the final ACK.

Refer to [RFC 793] - TCP - Transmission Control Protocol for more information about TCP states.
4.2.66  IP_TCP_SetConnKeepaliveOpt()

Description
Sets the keepalive options.

Prototype

```c
void IP_TCP_SetConnKeepaliveOpt ( U32 Init,
       U32 Idle,
       U32 Period,
       U32 MaxRep);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Init</td>
<td>Maximum time after TCP-connection open (response to SYN) in ms in case no data transfer takes place. The embOS/IP default is 10 seconds.</td>
</tr>
<tr>
<td>Idle</td>
<td>Time of TCP-inactivity before first keepalive probe is sent in ms. The embOS/IP default is 10 seconds.</td>
</tr>
<tr>
<td>Period</td>
<td>Time of TCP-inactivity between keepalive probes in ms. The embOS/IP default is 10 seconds.</td>
</tr>
<tr>
<td>MaxRep</td>
<td>Number of keepalive probes before we give up and close the connection. The embOS/IP default is 8 repetitions.</td>
</tr>
</tbody>
</table>

Additional information

Keepalives are not part of the TCP specification, since they can cause good connections to be dropped during transient failures. For example, if the keepalive probes are sent during the time that an intermediate router has crashed and is rebooting, TCP will think that the client's host has crashed, which is not what has happened. Nevertheless, the keepalive feature is very useful for embedded server applications that might tie up resources on behalf of a client, and want to know if the client host crashes.

Keepalives will be sent if the TCP connection sits idle for \texttt{Idle} ms and will then start sending a keepalive each \texttt{Period} ms for \texttt{MaxRep}. Each time a keepalive is ACKed by the peer, the next keepalive will again be sent after \texttt{Idle} ms.

By design keepalives are retransmissions of already sent and ACKed data. Depending on the used IP stack a retransmit is typically one byte sent with the current sequence number - 1, so that the peer will discard the data itself as it has already been received and ACKed but will send an ACK back to notify the sender that it has been received and to not send it again.

Other stacks might even send a TCP packet with zero data and the current sequence number, forcing the other side to practically answer back to a duplicate ACK. Keepalives might not be displayed correctly by tools like Wireshark. A zero length keepalive is typically seen like a duplicate ACK while a one byte keepalive might actually be a one byte retransmit if sending chunks of one byte and one of them has not been ACKed.

The \texttt{Init} value configured is the connect timeout that will be used for \texttt{connect()}. 
4.2.67  IP_TCP_SetRetransDelayRange()

Description
Sets retransmission delay range.

Prototype

```c
void IP_TCP_SetRetransDelayRange(unsigned RetransDelayMin,
                                unsigned RetransDelayMax);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RetransDelayMin</td>
<td>Minimum time before first retransmission. The embOS/IP default is 200 ms.</td>
</tr>
<tr>
<td>RetransDelayMax</td>
<td>Maximum time to wait before a retransmission. The embOS/IP default is 3 seconds.</td>
</tr>
</tbody>
</table>

Additional information
TCP is a reliable transport layer. One of the ways it provides reliability is for each end to acknowledge the data it receives from the communication partner. But data segments and acknowledgments can get lost. TCP handles this by setting a timeout when it sends data, and if the data is not acknowledged when the timeout expires, it retransmits the data. The timeout and retransmission is the measurement of the round-trip time (RTT) experienced on a given connection. The RTT can change over time, as routes might change and as network traffic changes, and TCP should track these changes and modify its timeout accordingly. IP_TCP_SetRetransDelayRange() should be called if the default limits are not sufficient for your application.
4.2.68 IP_UDP_Add()

Description
Adds UDP Protocol support to the stack.

Prototype

```c
void IP_UDP_Add(void);
```

Additional information

`IP_UDP_Add()` adds UDP to the stack. The function should be called during the initialization of the stack. In the supplied sample configuration files `IP_UDP_Add()` is called from `IP_X_Config()`. If you remove the call of `IP_UDP_Add()`, the UDP code will not be available in your application.
4.2.69  IP_UDP_AddEchoServer()

Description
Adds a simple echo server for UDP packets that can be used for UDP pings and other tests.

Prototype

IP_UDP_CONNECTION *IP_UDP_AddEchoServer(U16 LPort);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LPort</td>
<td>Local port on which to listen for incoming packets.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL       O.K. Pointer to the connection.
= NULL       Error.

Additional information

The echo server will simply send back the incoming packet to the sender.
4.2.70 IP_UDP_DisableRxChecksum()

**Description**
Disables checksum verification of the checksum in the UDP header for incoming packets.

**Prototype**
```c
void IP_UDP_DisableRxChecksum(void);
```

**Additional information**
In a typical network all data contained in a transferred frame have already been verified by the hardware checking the transmitted frames checksum and it is unlikely that data within this frame are corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.2.71 IP_UDP_EnableRxChecksum()

Description
Enables checksum verification of the checksum in the TCP header for incoming packets.

Prototype

```c
void IP_UDP_EnableRxChecksum(void);
```

Additional information
In a typical network all data contained in a transferred frame have already been verified by the hardware checking the transmitted frames checksum and it is unlikely that data within this frame are corrupted if the frame checksum was verified as being correct. Therefore for optimization reasons the checksum calculation might be disabled.
4.3 Configuration functions (IP fragmentation)
4.3.1  IP_FRAGMENT_ConfigRx()

Description
Modifies the embOS/IP default settings for IPv4 fragmentation.

Prototype

```c
void IP_FRAGMENT_ConfigRx(U16 MaxFragments,
                          U32 Timeout,
                          U8  KeepOOO);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxFragments</td>
<td>Maximum number of fragments which are allowed for a fragmented packet.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout [ms] before discarding fragment queues.</td>
</tr>
</tbody>
</table>
| KeepOOO     | Keep Out Of Order fragments.  
• 0: Discard (default).  
• 1: Keep. |
4.3.2  IP_FRAGMENT_Enable()

Description
Initializes the required variables and adds a timer to the stack to handle outdated fragment queues.

Prototype

```c
void IP_FRAGMENT_Enable(void);
```
4.3.3  IP_IPV6_FRAGMENT_ConfigRx()

Description

Modifies the default settings for IPv6 fragmentation.

Prototype

```c
void IP_IPV6_FRAGMENT_ConfigRx ( U16 MaxFragments,
                                  U32 Timeout,
                                  U8  KeepOOO);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxFragments</td>
<td>Maximum number of fragments which are allowed for a fragmented packet.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout [ms] before discarding fragment queues.</td>
</tr>
</tbody>
</table>
| KeepOOO | Keep Out Of Order fragments.  
  • 0: Discard (default).  
  • 1: Keep. |
4.3.4 IP_IPV6_FRAGMENT_Enable()

Description
Initializes the required variables and adds a timer to the stack to handle outdated fragment queues.

Prototype

void IP_IPV6_FRAGMENT_Enable(void);
4.4 Management functions
4.4.1 IP_DeInit()

Description
Deinitializes the TCP/IP stack.

Prototype
void IP_DeInit(void);

Additional information
IP_DeInit() de-initializes the IP stack. This function should be the very last embOS/IP function called and is typically not needed if you do not need to shutdown your whole application for a special reason.

De-initialization should be done in the exact reversed order of initialization. This means terminating any created task that uses the IP API, terminating the IP_RxTask (if used), terminating the IP_Task and finally calling IP_DeInit() to close down the stack. The whole de-initialization should be done with Ethernet interrupts disabled and task switching disabled to prevent the de-initialization being interrupted by an Ethernet event.

De-init has to be supported by the driver as well. If your driver does not yet support IP_DeInit() you will end up in IP_Panic(). Please contact our support address and ask for IP_DeInit() support to be added to your driver.

Example

```c
#include "IP.h"

void main(void) {
    IP_Init();
    //
    // Create IP tasks and use the stack
    // ...
    //
    // Disable Ethernet interrupt
    //
    OS_EnterRegion(); // Prevent task switching
    //
    // Terminate all application tasks that make use of the IP API
    //
    //
    // Terminate IP_RxTask first (if used) and IP_Task
    //
    IP_DeInit();
    OS_LeaveRegion(); // Allow task switching
}
```
4.4.2 IP_Init()

Description
Initializes the TCP/IP stack.

Prototype

```c
void IP_Init(void);
```

Additional information
IP_Init() initializes the IP stack and creates resources required for an OS integration. This function must be called before any other embOS/IP function is called.

Example

```c
#include "IP.h"

void main(void) {
    IP_Init();
    /*
    * Use the stack
    */
}
```
CHAPTER 4
Management functions

4.4.3 IP_Task()

Description
Main task for starting the stack. After startup, it settles into a loop handling received packets. This loop sleeps until a packet has been queued in the receive queue; then it should be awakened by the driver which queued the packet.

Prototype

void IP_Task(void);

Additional information
Implementing this task is the simplest way to include embOS/IP into your project. Typical stack usage is defined in TASK_STACK_SIZE_IP_TASK.

Note: The priority of task IP_Task should be higher than the priority of an application task which uses the stack.

Example

```c
#include <stdio.h>
#include "RTOS.h"
#include "BSP.h"
#include "IP.h"
#include "IP_Int.h"

static OS_STACKPTR int _Stack0[512]; // Task stacks
static OS_TASK _TCB0;               // Task-control-blocks
static OS_STACKPTR int _IPStack[1024]; // Task stacks
static OS_TASK _IPTCB;               // Task-control-blocks

/*********************************************************************
*       MainTask
*/
void MainTask(void);
void MainTask(void) {
    printf("****************************************
Program start
");
    IP_Init();
    OS_SetPriority(OS_GetTaskID(), 255); // This task has highest prio!
    OS_CREATETASK(&_IPTCB, "IP_Task", IP_Task, 150, _IPStack);
    while (1) {
        BSP_ToggleLED(1);
        OS_Delay (200);
    }
}

/*********************************************************************
*       main
*/
void main(void) {
    BSP_Init();
    BSP_SetLED(0);
    OS_IncDI(); // Initially disable interrupts *
    OS_InitKern(); // initialize OS *
    OS_InitHW(); // initialize Hardware for OS *
    OS_CREATETASK(&_TCB0, "MainTask", MainTask, 100, _Stack0);
    OS_Start();
}
```
4.4.4 IP_RxTask()

Description
The task reads all available packets from the network interface and sleeps until a new packet is received.

Prototype

```c
void IP_RxTask(void);
```

Additional information
This task is optional. Refer to Tasks and interrupt usage on page 44 for detailed information about the task and interrupt handling of embOS/IP. Typical stack usage is defined in TASK_STACK_SIZE_IP_RX_TASK.

Note:
The priority of task IP_RxTask() should be higher than the priority of an application task which uses the stack.
4.4.5 IP_Exec()

Description
Checks if the driver has received a packet and handles timers.

Prototype

I32 IP_Exec(void);

Return value
Value of the next timeout.

Additional information
This function is normally called from an endless loop in IP_Task(). If no particular IP task is implemented in your project, IP_Exec() should be called regularly.
4.5 Network interface configuration and handling functions
4.5.1 IP_NI_AddPTPDriver()

Description
Adds a PTP driver for HW timestamp support.

Prototype

```c
int IP_NI_AddPTPDriver(       unsigned            IFaceId ,
                              const  IP_HW_PTP_DRIVER *  pPTPDriver ,
                              U32                CoreClock );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pPTPDriver</td>
<td>PTP driver to add.</td>
</tr>
<tr>
<td>CoreClock</td>
<td>CPU clock [Hz] of the system. Can not be 0.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>Error, not supported</td>
</tr>
<tr>
<td>0</td>
<td>OK</td>
</tr>
<tr>
<td>1</td>
<td>Error, called after driver initialization has been completed.</td>
</tr>
</tbody>
</table>
4.5.2  IP_NI_ClrBPressure()

Description
Disables usage of back pressure (sending a jam signal to signal when we run into a shortage where the hardware can not receive more data).

Prototype

```c
void IP_NI_ClrBPressure(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
4.5.3  IP_NI_ConfigPoll()

Description
Select polled mode for the network interface. This should be used only if the NI can not activate an ISR itself.

Prototype

void IP_NI_ConfigPoll(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
4.5.4  IP_NI_ForceCaps()

Description

Allows to force capabilities to be set for an interface. Typically this is used to allow the checksum calculation capabilities to be set manually. Typically this is used to give the target a performance boost in high traffic applications on stable networks, where the occurrence of wrong checksums is unlikely.

Prototype

```c
void IP_NI_ForceCaps(unsigned IFaceId,
            U8   CapsForcedMask,
            U8   CapsForcedValue);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based index network interfaces.</td>
</tr>
<tr>
<td>CapsForcedMask</td>
<td>Defines which bits in the Caps byte will be modified. A 1 in the mask will allow the Caps to be modified by the corresponding bit in CapsForcedValue.</td>
</tr>
<tr>
<td>CapsForcedValue</td>
<td>Values for the corresponding bits in CapsForcedMask. Usually an OR of the following values:</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_WRITE_IP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_WRITE_UDP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_WRITE_TCP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_WRITE_ICMP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_CHECK_IP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_CHECK_UDP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_CHECK_TCP_CHKSUM</td>
</tr>
<tr>
<td></td>
<td>• IP_NI_CAPS_CHECK_ICMP_CHKSUM</td>
</tr>
</tbody>
</table>

Example

Forcing the capability bits 0 to value ‘0’ and bit 2 to value ‘1’ for the first interface can be done as shown in the code example below:

```c
IP_NI_ForceCaps(0, 5, 4);
```
4.5.5 IP_NI_SetBPressure()

Description
Enables usage of back pressure (sending a jam signal to signal when we run into a shortage where the hardware can not receive more data).

Prototype

```c
void IP_NI_SetBPressure(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
4.5.6  IP_NI_SetTxBufferSize()

Description
Sets the size of the Tx buffer of the network interface.

Prototype

```c
int IP_NI_SetTxBufferSize(unsigned IFaceId,
                         unsigned NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Size of the Tx buffer (at least size of the MTU + 16 bytes for Ethernet).</td>
</tr>
</tbody>
</table>

Return value

-1  Error, not supported
0   OK
1   Error, called after driver initialization has been completed.

Additional information

The default Tx buffer size is 1536 bytes. It can be useful to reduce the buffer size on systems with less RAM and an application that uses a small MTU. According to RFC 576 bytes is the smallest possible MTU. The size of the Tx buffer should be at least MTU + 16 bytes for Ethernet header and footer. The function should be called in IP_X_Config().

Note:

This function is not implemented in all network interface drivers, since not all Media Access Controllers (MAC) support variable buffer sizes.
4.6 PHY configuration functions
### 4.6.1  IP_NI_ConfigPHYAddr()

**Description**

Configure the PHY Addr.

**Prototype**

```c
void IP_NI_ConfigPHYAddr ( unsigned IFaceId ,
                           U8       Addr );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface number.</td>
</tr>
<tr>
<td>Addr</td>
<td>5-bit address.</td>
</tr>
</tbody>
</table>

**Additional information**

The PHY address is a 5-bit value. The available embOS/IP drivers try to detect the PHY address automatically, therefore this should not be called. If you use this function to set the address explicitly, the function must be called from within `IP_X_Config()`.
4.6.2  IP_NI_ConfigPHYMode()

Description
Configure the PHY mode.

Prototype

```c
void IP_NI_ConfigPHYMode(unsigned IFaceId, 
U8 Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface number.</td>
</tr>
<tr>
<td>Mode</td>
<td>The operating mode of the PHY.</td>
</tr>
</tbody>
</table>

Valid values for parameter Mode

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PHY_MODE_MII</td>
<td>Phy uses the Media Independent Interface (MII).</td>
</tr>
<tr>
<td>IP_PHY_MODE_RMII</td>
<td>Phy uses the Reduced Media Independent Interface (RMII).</td>
</tr>
</tbody>
</table>

Additional information

The PHY can be connected to the MAC via two different modes, MII or RMII. Refer to section MII / RMII: Interface between MAC and PHY on page 48 for detailed information about the differences of the MII and RMII modes.

The selection which mode is used is normally done correctly by the hardware. The mode is typically sampled during power-on RESET. If you use this function to set the mode explicitly, the function must be called from within IP_X_Config(). Refer to IP_X_Config on page 527.
### 4.6.3 IP_PHY_AddDriver()

**Description**

Adds a PHY driver and assigns it to an interface.

**Prototype**

```c
void IP_PHY_AddDriver( unsigned IFaceId,
                        const IP_PHY_HW_DRIVER * pDriver,
                        const void              * pAccess,
                        IP_PHY_pfConfig pf);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pDriver</td>
<td>Pointer to driver function table.</td>
</tr>
<tr>
<td>pAccess</td>
<td>Pointer to function table containing routines for hardware access, depending on the driver to add.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to PHY config routine.</td>
</tr>
</tbody>
</table>

**Additional information**

If a driver has already been added for the selected interface the driver will not be overwritten. The same applies for the hardware access functions and the config callback. This allows settings different parameters like the driver and access routines from different places.

Typically the network interface driver will try to add the generic PHY driver so it is not necessary to update an existing `IP_X_Config()` unless new `IP_PHY_*` functions shall be used or a driver other than the generic PHY driver shall be used.

**Example**

The following is an excerpt from an `IP_Config_*`.c file:

```c
/******************************************************************************
*  _ConfigPHY()
*  Function description
*    Callback executed during the PHY init of the stack to configure PHY settings once the hardware interface has been initialized.
*  Parameters
*    IFaceId: Zero-based interface index.
******************************************************************************
static void _ConfigPHY(unsigned IFaceId) {
    // Further PHY configuration can be added here by calling
    // IP_PHY_*() functions for generic or specific PHY configuration.
    
}

/******************************************************************************
*  IP_X_Config()
*  Function description
*    This function is called by the IP stack during IP_Init().
******************************************************************************
void IP_X_Config(void) {
    ...
```
// Add the generic PHY driver for interface #0 and register
// a PHY config routine executed when the PHY driver is initialized.
//
IP_PHY_AddDriver(0, &IP_PHY_Driver_Generic, NULL, &_ConfigPHY);
...
}
4.6.4 IP_PHY_AddResetHook()

Description

This function adds a hook function to the IP_HOOK_ON_PHY_RESET list. Registered hooks will be called after a PHY reset has been executed and the generic init has been finished. This allows the user to apply further settings to the PHY if needed.

Prototype

```c
void IP_PHY_AddResetHook (IP_HOOK_ON_PHY_RESET * pHook,
                          IP_NI_pfOnPhyReset pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to static element of IP_HOOK_ON_PHY_RESET that can be internally used by the stack.</td>
</tr>
<tr>
<td>pf</td>
<td>Function pointer to the callback that will be executed.</td>
</tr>
</tbody>
</table>

Additional information

In some cases it might be necessary to apply a custom configuration to the PHY. The generic PHY module used by the stack in most cases will only apply a minimal configuration. Registering a callback custom settings can be applied to this configuration.

If you are changing the PHY register page you need to reset it back to page 0 before returning from the callback.

Example

```c
// Excerpt of content of IP_Config_* . c
//
static IP_HOOK_ON_PHY_RESET _Hook;

/***************************************************************************/
/* _OnPhyReset() */
/***************************************************************************/
static void _OnPhyReset (unsigned IFaceId, void *pContext, const IP_PHY_API *pApi) {
    U16 v;
    v = pApi->pfRead (pContext, 0); // Read PHY register 0.
    ... // Modify value read.
    pApi->pfWrite (pContext, 0, v); // Write modified value back to PHY register 0.
}

void IP_X_Config (void) {
    ...
    IP_PHY_AddResetHook (&_Hook, _OnPhyReset); // Register _OnPhyReset() to be executed after a PHY software reset.
    ...
```
4.6.5 IP_PHY_ConfigAddr()

Description
Configures the PHY address to use.

Prototype

```c
void IP_PHY_ConfigAddr(unsigned IFaceId, unsigned Addr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Addr</td>
<td>PHY address.</td>
</tr>
</tbody>
</table>

Additional information
New version of the old function IP_NI_ConfigPHYAddr() that makes direct use of the PHY module.
4.6.6 IP_PHY_ConfigAltAddr()

Description
Sets a list of PHY addresses that can alternately be checked for the link state.

Prototype

```c
void IP_PHY_ConfigAltAddr( unsigned IFaceId,
                         const IP_PHY_ALT_LINK_STATE_ADDR * pAltPhyAddr );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pAltPhyAddr</td>
<td>List of alternate PHY addresses.</td>
</tr>
</tbody>
</table>

Additional information

A typical setup would be using a switch where the first PHY/port uses the PHY addr. 0x01 and the second PHY/port uses the addr. 0x02. The PHY driver by default might only support one addr. to check the link state (e.g. on PHY addr. 0x01) and will ignore the link state on any other PHY addr. Using this alternate list of addr. these will be checked as well if supported by the driver.

Example

```c
// PHY addresses of switch ports 2 - 4 (port 1 with addr. 0x01 will be found automatically).
const U8 aAltPhyAddr[] = { 0x02, 0x03, 0x04 };

const IP_PHY_ALT_LINK_STATE_ADDR AltPhyAddr = {
    aAltPhyAddr,
    SEGGER_COUNTOF(aAltPhyAddr)
};

void IP_X_Config(void) {
    ... 
    IFaceId = IP_AddEtherInterface(DRIVER);
    IP_PHY_ConfigAltAddr(IFaceId, &AltPhyAddr);
    ... 
} 
```
4.6.7    IP_PHY_ConfigGigabitSupport()

Description
Configures if the MAC supports Gigabit Ethernet. If the MAC does not support Gigabit Ethernet (default) then the PHY driver does not have to handle it in case it is not supported anyhow.

Prototype

```c
void IP_PHY_ConfigGigabitSupport(unsigned IFaceId,
                                 unsigned OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0: MAC does not support Gigabit Ethernet.  
           | • 1: MAC supports Gigabit Ethernet. If the PHY is Gigabit capable as well it can be used. |

Additional information
Typically only required if a PHY driver other than the generic PHY driver is used.
4.6.8 IP_PHY_ConfigSupportedModes()

Description
Configures the duplex and speed modes that shall be supported. Typically the supported modes are the modes supported by the MAC.

Prototype

```c
void IP_PHY_ConfigSupportedModes(unsigned IFaceId,
                                  unsigned Modes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| Modes     | ORRed value of the following supported modes:  
            • IP_PHY_MODE_10_HALF  
            • IP_PHY_MODE_10_FULL  
            • IP_PHY_MODE_100_HALF  
            • IP_PHY_MODE_100_FULL  
            • IP_PHY_MODE_1000_HALF  
            • IP_PHY_MODE_1000_FULL |

Additional information

New version of the old function IP_SetSupportedDuplexModes() that makes direct use of the PHY module.
4.6.9 IP_PHY_ConfigUseStaticFilters()

Description
Tells the stack if using PHY static MAC filter is allowed.

Prototype

```c
void IP_PHY_ConfigUseStaticFilters(unsigned IFaceId, unsigned OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0: Do not use the PHY static filters.  
|           | • 1: Use the PHY static filters. |

Additional information
By default the stack is allowed to use PHY filters if available. Can be disabled using this function if a custom filtering by the user shall be used.
Needs to be used with a hardware interface (typically #0). Does have no effect when being used with virtual interfaces like Tail Tagging interfaces.
4.6.10  IP_PHY_DisableCheck()

Description
Disables PHY checks for all interfaces. This might be necessary for some PHYs that are not fully IEEE 802.3u compliant.

Prototype

```c
void IP_PHY_DisableCheck(U32 Mask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mask</td>
<td>Bitwise-OR bit mask of checks to disable:</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_CHECK_ID</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_CHECK_LINK_STATE_AFTER_UP</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_WATCHDOG</td>
</tr>
</tbody>
</table>
4.6.11 IP_PHY_DisableCheckEx()

Description
Disables PHY checks for one interface. This might be necessary for some PHYs that are not fully IEEE 802.3u compliant.

Prototype

```c
void IP_PHY_DisableCheckEx(unsigned IFaceId,
                            U32 Mask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Mask</td>
<td>Bitwise-OR bit mask of checks to disable:</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_CHECK_ID</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_CHECK_LINK_STATE_AFTER_UP</td>
</tr>
<tr>
<td></td>
<td>• PHY_DISABLE_WATCHDOG</td>
</tr>
</tbody>
</table>
4.6.12    IP PHY ReInit()

Description
Re-initializes the PHY.

Prototype

```c
void IP_PHY_ReInit(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
### 4.6.13  IP_PHY_SetWdTimeout()

**Description**
Sets the watchdog timeout for watching if the PHY reached an unstable state.

**Prototype**

```c
void IP_PHY_SetWdTimeout (int ShiftCnt);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ShiftCnt</td>
<td>Timeout comparison mask is ((1 \ll \text{ShiftCnt}) - 1).</td>
</tr>
</tbody>
</table>

**Additional information**

For optimization reasons the comparison is done by using a bitmask instead of a division. The bitmask is not allowed to contain a zero bit on a lower value position than a one bit. To reach this we pass a shift count instead of a typical timeout.

A PHY watchdog timeout might occur due to a link down of the interface if it had a link up before. In this case the stack resets the PHY as well to make sure it is not in a bad state and is kept functional.
4.7 Statistics functions
4.7.1  IP_STATS_EnableIFaceCounters()

Description
Enables statistic counters for a specific interface.

Prototype
void IP_STATS_EnableIFaceCounters(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.2 IP_STATS_GetIFaceCounters()

Description
Retrieves a pointer to the statistic counters for a specific interface.

Prototype
IP_STATS_IFACE *IP_STATS_GetIFaceCounters(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Success: Pointer to structure of type IP_STATS_IFACE. Error: NULL

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.3  IP_STATS_GetLastLinkStateChange()

**Description**
Retrieves the tick count when an interface entered its current state.

**Prototype**

```c
U32 IP_STATS_GetLastLinkStateChange(unsigned IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Return value**
Timestamp in system ticks (typically 1ms).

**Additional information**

IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.4 IP_STATS_GetRxBytesCnt()

Description
Retrieves the number of bytes received on an interface.

Prototype
U32 IP_STATS_GetRxBytesCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of bytes received on this interface.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.5 IP_STATS_GetRxDiscardCnt()

Description
Retrieves the number of packets received but discarded although they were O.K.

Prototype
U32 IP_STATS_GetRxDiscardCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of packets received but discarded although they were O.K.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.6  IP_STATS_GetRxErrCnt()

Description
Retrieves the number of receive errors.

Prototype
U32 IP_STATS_GetRxErrCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of receive errors.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.7 IP_STATS_GetRxNotUnicastCnt()

Description
Retrieves the number of packets received on an interface that were not unicasts.

Prototype
U32 IP_STATS_GetRxNotUnicastCnt( unsigned IFaceId );

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of packets received on this interface that were not unicasts.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.8   IP_STATS_GetRxUnicastCnt()

Description
Retrieves the number of unicast packets received on an interface.

Prototype
U32 IP_STATS_GetRxUnicastCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of unicast packets received on this interface.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.9  IP_STATS_GetRxUnknownProtoCnt()

Description
Retrieves the number of unknown protocols received.

Prototype

U32 IP_STATS_GetRxUnknownProtoCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of unknown protocols received.

Additional information

IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.10 IP_STATS_GetTxBytesCnt()

Description
Retrieves the number of bytes sent on an interface.

Prototype
U32 IP_STATS_GetTxBytesCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of bytes sent on this interface.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.11 IP_STATS_GetTxDiscardCnt()

Description
Retrieves the number of packets to send but discarded although they were O.K. .

Prototype
U32 IP_STATS_GetTxDiscardCnt(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of packets to send but discarded although they were O.K. .

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
### 4.7.12 IP_STATS_GetTxErrCnt()

**Description**
Retrieves the number of send errors on an interface.

**Prototype**
```c
U32 IP_STATS_GetTxErrCnt(unsigned IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Return value**
Number of send errors.

**Additional information**
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.13   IP_STATS_GetTxNotUnicastCnt()

Description
Retrieves the number of packets sent on an interface that were not unicasts.

Prototype
U32 IP_STATS_GetTxNotUnicastCnt (unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of packets sent on this interface that were not unicasts.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.7.14 IP_STATS_GetTxUnicastCnt()

Description
Retrieves the number of unicast packets sent on an interface.

Prototype
U32 IP_STATS_GetTxUnicastCnt(unsigned IFaceId);

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Number of unicast packets sent on this interface.

Additional information
IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.8 Other IP Stack functions
4.8.1 IP_AddAfterInitHook()

Description

Adds a hook to a callback that is executed at the end of IP_Init() to allow adding initializations to be executed right after the stack itself has been initialized and all API can be used.

Prototype

void IP_AddAfterInitHook(IP_HOOK_AFTER_INIT * pHook,  
                       void (*pf)());

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to static element of IP_HOOK_AFTER_INIT that can be internally used by the stack.</td>
</tr>
<tr>
<td>pf</td>
<td>Function pointer to the callback that will be executed.</td>
</tr>
</tbody>
</table>

Additional information

Adding a callback to be executed right after IP_Init() can be helpful for various things. For example this allows using a centralized initialization that is not located in the main routine that calls IP_Init() and has to make use of IP API that is only valid to be used after IP_Init().

Example

```c
// Excerpt of content of IP_Config_*.c
//
static IP_HOOK_AFTER_INIT _Hook;

static void _Connect(void) {
    ...
}

void IP_X_Config(void) {
    ...
    IP_AddAfterInitHook(&_Hook, _Connect);  // Register _Connect() to be executed at end of IP_Init()
    ...
}

// Excerpt of content of main.c
//
void main(void) {
    ...
    IP_Init();
    ...
}  
```
4.8.2 IP_AddEtherTypeHook()

Description
This function registers a callback to be called for received packets with the registered Ethernet type.

Prototype

```c
void  IP_AddEtherTypeHook
     ( IP_HOOK_ON_ETH_TYPE *  pHook ,
       int                    (  * pf )
             ( unsigned  IFaceId ,  IP_PACKET *  pPacket ,  void *  pBuffer ,  U32 NumBytes ),
       U16                   Type );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Hook resource of type IP_HOOK_ON_ETH_TYPE.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to call for the registered Ethernet type.</td>
</tr>
<tr>
<td>Type</td>
<td>Ethernet type that triggers the callback in host endianess.</td>
</tr>
</tbody>
</table>

Example

```c
static  IP_HOOK_ON_ETH_TYPE _Hook ;

/*******************************************************************************/
/*
 * _OnARP()
 */

Function description
* This function allocates a packet to mirror back a received ARP packet to the network. This is of no use but demonstrates how to use the API.
* The received packet will be handled regularly by the stack as well by returning IP_OK_TRY_OTHER_HANDLER.
* 
* Parameters
* IFaceId : Zero-based interface index.
* pPacket : Pointer to received packet.
* pBuffer : Pointer to start of data of the received packet.
* NumBytes: NumBytes data received in the packet.
* 
* Return value
* Original packet has not been changed and the stack shall process it: IP_OK_TRY_OTHER_HANDLER
* Original packet has been freed or reused by the callback: Other like IP_OK or IP_RX_ERROR.
*/

static  int  _OnARP ( unsigned  IFaceId , IP_PACKET *  pPacket , void *  pBuffer , U32 NumBytes )  {
  IP_PACKET *  pPacketOut ;
  U8 *         p ;

  pPacketOut =  IP_AllocEtherPacket ( IFaceId ,  NumBytes ,  & p ) ;
  if  ( pPacketOut !=  NULL )  {
    IP_MEMCPY ( p ,  pBuffer ,  NumBytes ) ;
    IP_SendEtherPacket ( IFaceId ,  pPacketOut ,  NumBytes ) ;
  }
  return  IP_OK_TRY_OTHER_HANDLER ;
}

/*******************************************************************************/
/*
 * MainTask()
 */
```
*/
void MainTask(void) {
    IP_Init();
    IP_AddEtherTypeHook(&_Hook, _OnARP, 0x0806);
    ...
}
4.8.3 IP_AddLinkChangeHook()

Description
 Adds a callback that gets executed each time the link state changes.

Prototype

void IP_AddLinkChangeHook ( IP_HOOK_ON_LINK_CHANGE * pHook,
   void                      ( * pf)
( unsigned IFaceId , U32 Duplex , U32 Speed ));

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Management element of type IP_HOOK_ON_LINK_CHANGE.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to execute on a link state change.</td>
</tr>
</tbody>
</table>

Example

```c
static IP_HOOK_ON_LINK_CHANGE _Hook;

static void _OnLinkChange(unsigned IFaceId, U32 Duplex, U32 Speed) {
   ...
}

void main(void) {
   ...
   IP_AddLinkChangeHook(&_Hook, _OnLinkChange); // Register _OnLinkChange() to be
   // executed when interface changes.
   // Connect dial-up interface.
   ...
}
```
4.8.4 IP_AddOnPacketFreeHook()

Description
This function adds a hook function to the IP_HOOK_ON_PACKET_FREE list. Registered hooks will be called in case a packet gets freed.

Prototype

```c
void IP_AddOnPacketFreeHook ( IP_HOOK_ON_PACKET_FREE * pHook ,
                          void                      ( * pf )( IP_PACKET * pPacket ));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Element of type IP_HOOK_ON_PACKET_FREE to register.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback that is notified on a packet free.</td>
</tr>
</tbody>
</table>
4.8.5 IP_AddStateChangeHook()

**Description**

Adds a hook to a callback that is executed when the AdminState or HWState of an interface changes.

**Prototype**

```c
void IP_AddStateChangeHook( IP_HOOK_ON_STATE_CHANGE * pHook,
                                  void (*pf)(unsigned IFaceId, U8 AdminState, U8 HWState ));
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to static element of IP_HOOK_ON_STATE_CHANGE that can be internally used by the stack.</td>
</tr>
<tr>
<td>pf</td>
<td>Function pointer to the callback that will be executed.</td>
</tr>
</tbody>
</table>

**Additional information**

A state change hook can be used to be notified about an interface disconnect that has not been triggered by the application. Typical example would be a peer that closes a dial-up connection and the application needs to get notified of this event to call a disconnect itself. Examples of this behavior can be found in the samples shipped with the stack.

**Example**

```c
static IP_HOOK_ON_STATE_CHANGE _Hook;

static void _OnChange(unsigned IFaceId, U8 AdminState, U8 HWState) {
...
}

void main(void) {
...
    IP_AddStateChangeHook(&_Hook, _OnChange); // Register _OnChange() to be executed when interface changes.
    // Connect dial-up interface.
    ...
}
```
4.8.6 IP_Alloc()

Description
Thread safe memory allocation from main IP stack memory pool.

Prototype

```c
void *IP_Alloc(U32 NumBytesReq);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytesReq</td>
<td>Number of bytes to allocate.</td>
</tr>
</tbody>
</table>

Return value

- `NULL`   Error.
- `≠ NULL`  O.K. Pointer to allocated memory

Additional information

Memory allocated with this function has to be freed with IP_Free().
4.8.7 IP_AllocEtherPacket()

Description

Allocates a packet to store the raw data of an Ethernet packet of up to `NumBytes` at the location returned by `ppBuffer`.

Prototype

```c
IP_PACKET *IP_AllocEtherPacket(unsigned IFaceId, U32 NumBytes, U8 ** ppBuffer);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Minimum buffer size the packet has to provide.</td>
</tr>
<tr>
<td>ppBuffer</td>
<td>Pointer where to store the pointer to the beginning of the packet buffer.</td>
</tr>
</tbody>
</table>

Return value

O.K. : Pointer to packet allocated. Error: NULL.
4.8.8  IP_AllocEx()

Description
Thread safe memory allocation from a specific memory pool managed by the stack that has been added using IP_AddMemory().

Prototype

```c
void *IP_AllocEx(U32 * pBaseAddr,
                 U32    NumBytesReq);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBaseAddr</td>
<td>Base address of the memory pool.</td>
</tr>
<tr>
<td>NumBytesReq</td>
<td>Number of bytes to allocate.</td>
</tr>
</tbody>
</table>

Return value

- = NULL  Error.
- ≠ NULL  O.K. Pointer to allocated memory

Additional information
Memory allocated with this function has to be freed with IP_Free().
4.8.9 IP_ARP_CleanCache()

Description
Cleans all ARP entries that are not static entries.

Prototype

void IP_ARP_CleanCache(void);
4.8.10  IP_ARP_CleanCacheByInterface()

Description
Cleans all ARP entries that are known to belong to a specific interface and are not static entries.

Prototype

void IP_ARP_CleanCacheByInterface(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
4.8.11 IP_Connect()

Description
Calls a previously registered hook for the interface if any was set using IP_SetIFaceConnectHook().

Prototype

\[ \text{int } \text{IP}_{-}\text{Connect}( \text{unsigned IFaceId}) ; \]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

= 0 O.K. or no callback set.
< 0 Error.
4.8.12 IP_Disconnect()

Description
Calls a previously registered hook for the interface if any was set using IP_SetIFaceDisconnectHook().

Prototype

```c
int IP_Disconnect(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

- = 0 O.K. or no callback set.
- < 0 Error.
4.8.13 IP_Err2Str()

Description
Converts IP stack error code to a readable string by simply using the defines name.

Prototype

```c
char *IP_Err2Str(int x);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Error code returned by API of the stack.</td>
</tr>
</tbody>
</table>

Return value

Pointer to string of the define name.
4.8.14 IP_FindIFaceByIP()

Description
Tries to find out the interface number when only the IP address is known.

Prototype

```c
int IP_FindIFaceByIP(void * pAddr,
                      unsigned Len);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAddr</td>
<td>Pointer to a variable holding the address to find in host endianness.</td>
</tr>
<tr>
<td>Len</td>
<td>Length of address at pAddr.</td>
</tr>
</tbody>
</table>

Return value

-1 Interface not found.
≥ 0 Interface found.

Additional information
For the moment only IPv4 is supported.

Example
The following sample tries to find an interface that has previously been configured to a fixed IP address of 192.168.2.10.

```c
int IFaceId;
U32 IPAddr;

IPAddr = IP_BYTES2ADDR(192, 168, 2, 10);
IFaceId = IP_FindIFaceByIP(&IPAddr, sizeof(IPAddr));
```
4.8.15  IP_Free()

Description
Thread safe memory free to IP stack memory pools.

Prototype

```c
void IP_Free(void * p);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>Pointer to memory block previously allocated with IP_Alloc().</td>
</tr>
</tbody>
</table>
4.8.16  IP_FreePacket()

**Description**
Frees a packet back to the stack.

**Prototype**

```c
void IP_FreePacket(IP_PACKET * pPacket);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Packet to free.</td>
</tr>
</tbody>
</table>

**Additional information**
This routine can be used to typically free any allocated packet regardless of the API used to allocate it.
4.8.17  IP_GetAddrMask()

Description
Retrieves the IP address and subnet mask of an interface. The values are stored in host bytes order. (for example, 192.168.1.1 is returned as \texttt{0xC0A80101}).

Prototype

\begin{verbatim}
void IP_GetAddrMask (U8 IFace,
                     U32 * pAddr,
                     U32 * pMask);
\end{verbatim}

Parameters

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Parameter & Description \\
\hline
IFace & Zero-based interface index. \\
pAddr & Address to store the IP address in host order. \\
pMask & Address to store the subnet mask in host order. \\
\hline
\end{tabular}
\end{table}
4.8.18  IP_GetCurrentLinkSpeed()

Description
Returns the current link speed of the first interface (interface ID 0).

Prototype
int IP_GetCurrentLinkSpeed(void);

Return value
Current link speed in Hertz.

Additional information
The application should check if the link is up before a packet will be sent. It can take 2-3 seconds till the link is up if the PHY has been reset.

Example

    //
    // Wait until link is up.
    //
    while (IP_GetCurrentLinkSpeed() == 0) {
        OS_IP_Delay(100);
    }
4.8.19  IP_GetCurrentLinkSpeedEx()

Description
Returns the current link speed of the requested interface.

Prototype

```c
int IP_GetCurrentLinkSpeedEx(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface number.</td>
</tr>
</tbody>
</table>

Return value

Current link speed in Hertz.

Additional information

The application should check if the link is up before a packet will be sent. It can take 2-3 seconds till the link is up if the PHY has been reset.

Example

```c
//
// Wait until link is up.
//
while (IP_GetCurrentLinkSpeedEx(0) == 0) {
  OS_IP_Delay(100);
}
```
4.8.20   IP_GetFreePacketCnt()

Description
Checks how many packets for a specific size or greater are currently available in the system.

Prototype

```
U32 IP_GetFreePacketCnt (U32 NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytes</td>
<td>Minimum size of packets to find.</td>
</tr>
</tbody>
</table>

Return value

Number of packets available for this size.
4.8.21 IP_GetIFaceHeaderSize()

Description
Retrieves the size of the header necessary for the transport medium that is used by a specific interface. Example: Ethernet: 14 bytes header + 2 bytes padding.

Prototype
U32 IP_GetIFaceHeaderSize(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
Size of header for this interface.
4.8.22  IP_GetGWAddr()

Description

Returns the gateway address of the interface in host endianess. (for example, 192.168.1.1 is returned as 0xc0a80101).

Prototype

U32 IP_GetGWAddr(U8 IFace);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

The gateway address of the interface.
4.8.23  IP_GetHWAddr()

Description
Returns the hardware address (Media Access Control address) of the interface.

Prototype

```c
void IP_GetHWAddr(unsigned IFaceId, 
                  U8 * pDest, 
                  unsigned Len);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pDest</td>
<td>Address of the buffer to store the 48-bit MAC address.</td>
</tr>
<tr>
<td>Len</td>
<td>Size of the buffer. Should be at least 6-bytes.</td>
</tr>
</tbody>
</table>
4.8.24   IP_GetIPAddr()

Description

Returns the IP address of the interface in host endianess. Example: 192.168.0.1 is returned as 0xc0a80001 for a big endian target, 0x0100a8c0 for a little endian target.

Prototype

U32 IP_GetIPAddr(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface number.</td>
</tr>
</tbody>
</table>

Return value

IP address of the interface in host endianess.

Example

```c
void PrintIFaceIPAddr(void) {
  char ac[16];
  U32 IPAddr;

  IPAddr = IP_GetIPAddr(0);
  IP_PrintIPAddr(ac, IPAddr, sizeof(ac));
  printf("IP Addr: %s\n", ac);
}
```
4.8.25  IP_GetIPPacketInfo()

Description
Returns the start address of the data part of an IP_PACKET.

Prototype

char  *IP_GetIPPacketInfo ( IP_PACKET *  pPacket );

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to an IP_PACKET structure.</td>
</tr>
</tbody>
</table>

Return value

> 0  Start address of the data part of the IP packet.
= 0  On failure

Example

```c
/**************************************************************************
*       _pfOnRxICMP
*/
static int  _pfOnRxICMP (IP_PACKET *  pPacket) {
  char  * pData;

  pData = IP_GetIPPacketInfo (pPacket);
  if(*pData == 0x08) {
    printf("ICMP echo request received!\n");
  }
  if(*pData == 0x00) {
    printf("ICMP echo reply received!\n");
  }
  return 0;
}
```
4.8.26  IP_GetRawPacketInfo()

Description
Returns the start address of the raw data of an IP_PACKET.

Prototype

```c
char *IP_GetRawPacketInfo(const IP_PACKET *pPacket,
                          U16    *pNumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to an IP_PACKET structure.</td>
</tr>
<tr>
<td>pNumBytes</td>
<td>Output length of the packet.</td>
</tr>
</tbody>
</table>

Return value

- > 0  Start address of the raw data part of the IP packet.
- = 0  On failure.
4.8.27  IP_GetVersion()

Description
Returns the version of the stack.

Prototype

```c
int IP_GetVersion(void);
```

Return value
Version number.

Additional information
The format of the version number: <Major><Minor><Minor><Revision><Revision>. For example, the return value 10201 means version 1.02a.
4.8.28  IP_ICMP_SetRxHook()

Description
Sets a hook function which will be called if target receives a ping packet.

Prototype
void  IP_ICMP_SetRxHook ( IP_RX_HOOK *  pfRxHook );

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pf</td>
<td>Pointer to the callback function of type IP_RX_HOOK.</td>
</tr>
</tbody>
</table>

Additional information
The return value of the callback function is relevant for the further processing of the ICMP packet. A return value of 0 indicates that the stack has to process the packet after the callback has returned. A return value of 1 indicates that the packet will be freed directly after the callback has returned.

Example

```c
/***************************************************************************/
/*       Local defines, configurable */
/***************************************************************************/
#define  HOST_TO_PING      0xC0A80101

/***************************************************************************/
/*       _pfOnRxICMP */
/***************************************************************************/
static  int    _pfOnRxICMP ( IP_PACKET *  pPacket )  {
    const  char  *  pData ;
pData =  IP_GetIPPacketInfo ( pPacket );
if (* pData ==  0x08 )  {
    printf ( "ICMP echo request received!
" );
}
if (* pData ==  0x00 )  {
    printf ( "ICMP echo reply received!
" );
}
return  0 ;  // Give packet back to the stack for further processing.
}

/***************************************************************************/
/*       PingTask */
/***************************************************************************/
void  PingTask ( void )  {
    int  Seq ;
    char  *  s =  "This is a ICMP echo request!" ;

    while  ( IP_IFaceIsReady ()  ==  0 )  {
        OS_Delay ( 50 );
    }
    IP_ICMP_SetRxHook ( _pfOnRxICMP );
    Seq =  1111 ;
    while  ( 1 )  {
        BSP_ToggleLED ( 1 ) ;
        OS_Delay ( 200 ) ;
        IP_SendPing ( htonl ( HOST_TO_PING ),  s ,  strlen ( s ),  Seq ++);
    }```
4.8.29 IP_IFaceIsReady()

Description
Checks if the interface is ready for usage. Ready for usage means that the target has a physical link detected and a valid IP address. Operates on interface 0.

Prototype

```c
int IP_IFaceIsReady(void);
```

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Network interface is ready.</td>
</tr>
<tr>
<td>0</td>
<td>Network interface is not ready.</td>
</tr>
</tbody>
</table>

Additional information

The application has to check if the link is up before a packet will be sent and if the interface is configured. If a DHCP server is used for configuring your target, this function has to be called to assure that no application data will be sent before the target is ready.

Example

```c
// Wait until interface is ready.
while (IP_IFaceIsReady() == 0) {
    OS_Delay(100);
}
```
### 4.8.30  IP_IFaceIsReadyEx()

**Description**
Checks if the specified interface is ready for usage. Ready for usage means that the target has a physical link detected and a valid IP address.

**Prototype**

```c
int IP_IFaceIsReadyEx(unsigned IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface number.</td>
</tr>
</tbody>
</table>

**Return value**

- 1: Interface is ready.
- 0: Interface is not ready.

**Additional information**

The application has to check if the link is up before a packet will be sent and if the interface is configured. If a DHCP server is used for configuring your target, this function has to be called to assure that no application data will be sent before the target is ready.

**Example**

```c
// Wait until second interface is ready.
while (IP_IFaceIsReadyEx(1) == 0) {
    OS_Delay(100);
}
```
4.8.31 IP_IsAllZero()

Description
Checks if there are zeros at the given pointer.

Prototype

```c
int IP_IsAllZero(const U8 * p,
                 unsigned    NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>Pointer to location to check for zeros.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes to check to be zero.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NOT all bytes are 0x00 at the pointer.</td>
</tr>
<tr>
<td>1</td>
<td>All bytes are 0x00 at the pointer.</td>
</tr>
</tbody>
</table>
4.8.32 IP_IsExpired()

Description
Checks if the given system timestamp has already expired.

Prototype

```c
int IP_IsExpired(I32 Time);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>System timestamp as used by OS abstraction layer.</td>
</tr>
</tbody>
</table>

Return value

- 1  **Time** has expired.
- 0  **Time** has not yet expired.

Example

```c
U32 Timeout;

// Get current system time [ms] and timeout in one second.
//
Timeout = IP_OS_GET_TIME() + 1000;
//
// Wait until timeout expires.
//
do {
    OS_Delay(1);
} while (IP_IsExpired(Time) == 0);
```
4.8.33  IP_NI_ConfigLinkCheckMultiplier()

Description
Configures the multiplier of the period between interface link checks typically executed each second.

Prototype

```c
int IP_NI_ConfigLinkCheckMultiplier(unsigned IFaceId, unsigned Multiplier);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Multiplier</td>
<td>Multiplier of the link check period (default 1s).</td>
</tr>
</tbody>
</table>

Return value

- = 0  O.K.
- ≠ 0  Error/Not supported.

Additional information

The default period between link checks is one second which is fine for reacting on a link change. For other interfaces like WiFi it might not be necessary to check for the link status each second or it might even be worth reducing link checks to a minimum if this interferes with packet transactions on the same interface like a single SPI.
4.8.34 IP_NI_GetAdminState()

Description
Retrieves the admin state of the given interface.

Prototype

```c
int IP_NI_GetAdminState(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interface disabled.</td>
</tr>
<tr>
<td>1</td>
<td>Interface enabled.</td>
</tr>
<tr>
<td>-1</td>
<td>Invalid interface ID.</td>
</tr>
</tbody>
</table>
4.8.35  IP_NI_GetIFaceType()

Description
Retrieves a short textual description of the interface type.

Prototype

```c
int IP_NI_GetIFaceType(unsigned IFaceId, char * pBuffer, U32 * pNumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to the buffer where to store the string.</td>
</tr>
<tr>
<td>pNumBytes</td>
<td>Pointer to the size of the buffer at pBuffer and where to</td>
</tr>
<tr>
<td></td>
<td>store the length of the string (without termination).</td>
</tr>
</tbody>
</table>

Return value

- = 0  O.K.
- ≠ 0  Error.

Additional information

If the buffer is big enough this function will terminate the string in the buffer as well. The length of the string is always stored at pNumBytes.

Example

```c
char ac[10];  // Should be big enough to hold all short interface descriptions.
U32 NumBytes;

// // Get the type of interface #0 .
// NumBytes = sizeof(ac);
IP_NI_GetIFaceType(0, &ac[0], &NumBytes);
printf("Interface #0 is of type \"%s\", &ac[0]);
```
4.8.36  IP_NI_GetState()

Description
Returns the hardware state of the interface.

Prototype

```c
int IP_NI_GetState(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Interface is down</td>
</tr>
<tr>
<td>1</td>
<td>Interface is up</td>
</tr>
<tr>
<td>-1</td>
<td>Invalid interface ID</td>
</tr>
</tbody>
</table>
4.8.37 IP_NI_SetAdminState()

Description
Sets the AdminState of the interface.

Prototype

```c
void IP_NI_SetAdminState(unsigned IFaceId,
       int AdminState);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>AdminState</td>
<td>Admin state to set.</td>
</tr>
<tr>
<td></td>
<td>• 0: DOWN</td>
</tr>
<tr>
<td></td>
<td>• 1: UP</td>
</tr>
</tbody>
</table>

Additional information

For most interfaces like Ethernet, WiFi and virtual interfaces like VLAN the state is UP by default. Connection oriented interfaces like PPP or PPPoE use the state for a connect request and therefore start with state DOWN.

Setting an interface like Ethernet to DOWN will try to disable this interface to the best possible. A software filter for interfaces with state DOWN discards packets that can not be filtered using other mechanisms.

- Best case: The Rx interrupt of the interface gets disabled, reducing the CPU load for the disabled interface.
- Worst case: Only software filtering is applied. The CPU load for processing incoming packets will remain like for an interface with state UP.
4.8.38  IP_NI_GetTxQueueLen()

Description
Retrieves the current length of the Tx queue of an interface.

Prototype

```c
int IP_NI_GetTxQueueLen(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

- \( \geq 0 \)  Current Tx queue length.
- \(< 0\)  Error.

Additional information

IP_SUPPORT_STATS_IFACE or IP_SUPPORT_STATS needs to be enabled.
4.8.39  IP_NI_PauseRxInt()

Description
Pauses the Rx interrupt of an interface by disabling it temporary. The Rx interrupt will be automatically re-enabled after the specified pause time.

Prototype

```c
int IP_NI_PauseRxInt(unsigned IFaceId,
                      U32    Pause);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Pause</td>
<td>Time to pause the Rx interrupt [ms].</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
< 0  Error or disable Rx interrupt not supported by driver.

Additional information

Can be called from an interrupt context!

While most of the API is using an API lock that can not be used from an interrupt, this API can be called from an interrupt context as this is the typical case when being flooded with incoming packets. Calling this API from a task might not succeed anymore as the CPU is held constantly busy by Rx interrupts.

Pausing the Rx interrupt of an interface can be used as countermeasure to flood situations. It does not prevent the flood of packets being received at the interface itself but avoids the situation where the CPU is busy all the time handling these packets. A certain portion of the flood might get preserved in hardware buffers and might therefore be received once the Rx interrupt gets re-enabled. This is typically quickly handled and still a better solution than being constantly held busy by the incoming flood traffic.
4.8.40 IP_PrintIPAddr()

Description
Convert a 4-byte IP address to a dots-and-number string.

Prototype

```c
int IP_PrintIPAddr(char * pBuffer,
                    U32   IPAddress,
                    int  BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBuffer</td>
<td>Pointer to a buffer where to store the string.</td>
</tr>
<tr>
<td>IPAddress</td>
<td>IPv4 address in host byte order.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of buffer at pBuffer. Should be at least 16 bytes to store xxx.xxx.xxx.xxx.</td>
</tr>
</tbody>
</table>

Return value

- > 0     Length of string stored into the buffer without string termination character.
- = 0     Buffer is too small.

Additional information

IPAddress is given in host order. Example: 192.168.0.1 is 0x0100A8000 for big endian targets 0xC0A80001 for little endian targets.

Example

```c
void PrintIPAddr(void) {
    U32 IPAddress;
    char ac[16];

    IPAddress = 0xC0A80001; // IP address: 192.168.0.1
    IP_PrintIPAddr(ac, IPAddress, sizeof(ac));
    printf("IP address: %s\n", ac); // Output: IP address: 192.168.8.1
}
```
4.8.41 IP_ResolveHost()

Description
Resolve a host name string to its IP address by using a configured DNS server.

Prototype

```c
int IP_ResolveHost(const char * sHost,
                    U32 * pIPAddr,
                    U32 ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sHost</td>
<td>Host name string to resolve.</td>
</tr>
<tr>
<td>pIPAddr</td>
<td>Pointer to where to store the resolved IP addr. in network order.</td>
</tr>
<tr>
<td>ms</td>
<td>Timeout in ms to wait for the DNS server to answer.</td>
</tr>
</tbody>
</table>

Return value

- `= 0` O.K., host name resolved.
- `< 0` Error: Could not resolve host name.

Additional information

In contrast to the standard socket function `gethostbyname()`, this function allows resolving a host name in a thread safe way and should therefore be used whenever possible. The retrieved IP address will be returned in network order so it can be directly used with the BSD socket API.
4.8.42   IP_SendEtherPacket()

Description
Sends a previously allocated Ethernet packet.

Prototype

```c
int  IP_SendEtherPacket(unsigned IFaceId,
                          IP_PACKET * pPacket,
                          U32         NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Previously allocated Ethernet packet to send.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes that have been stored in the packet buffer.</td>
</tr>
</tbody>
</table>

Return value

- $= 0$ O.K.
- $\neq 0$ Error.

Additional information

The packet gets freed by the stack whether the return code is success or error. The packet can not be reused by the application.
4.8.43   IP_SendPacket()

Description
Sends a user defined packet on the interface. The packet will not be modified by the stack. 
IP_SendPacket() allocates a packet control block (IP_PACKET) and adds it to the out queue 
of the interface.

Prototype

```c
int IP_SendPacket(unsigned IFace,
                  void   * pData,
                  int    NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to user data to send.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of data to send.</td>
</tr>
</tbody>
</table>

Return value

-1   Could not allocate a packet for sending.
0    Packet in out queue.
1    Interface can not send.
4.8.44  IP_SendPing()

Description
Sends a single ICMP echo request ("ping") to the specified host. Function uses always interface 0.

Prototype

```c
int IP_SendPing(U32 FHost, char * pData, unsigned NumBytes, U16 SeqNum);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FHost</td>
<td>4-byte IPv4 address in network endian byte order of the target.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer on the ping data, NULL if do not care.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of data to attach to ping request.</td>
</tr>
<tr>
<td>SeqNum</td>
<td>Ping sequence number.</td>
</tr>
</tbody>
</table>

Return value

- = 0  ICMP echo request was successfully sent.
- < 0  Error

Additional information

If you call this function with activated logging, the ICMP reply or (in case of an error) the error message will be sent to stdout. To enable the output of ICMP status messages, add the message type `IP_MTYPE_ICMP` to the log filter and the warn filter. Refer to `Debugging` on page 1163 for detailed information about logging.
4.8.45 IP_SendPingCheckReply()

**Description**

Sends a single ICMP echo request ("ping") to the specified host using the selected interface and waits for the reply.

**Prototype**

```c
int IP_SendPingCheckReply(U32 IFaceId,
                           U32 FHost,
                           char * pData,
                           unsigned NumBytes,
                           unsigned ms);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>FHost</td>
<td>4-byte IPv4 address in network endian byte order of the target.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer on the ping data, NULL if do not care.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of data to attach to ping request.</td>
</tr>
<tr>
<td>ms</td>
<td>Number of ms to wait for the reply.</td>
</tr>
</tbody>
</table>

**Return value**

- = 0          OK, ping sent and reply received.
- = IP_ERR_TIMEDOUT  Timeout, ping sent but no reply received.
- < 0          Error.

**Additional information**

If you call this function with activated logging, the ICMP reply or (in case of an error) the error message will be sent to stdout. To enable the output of ICMP status messages, add the message type `IP_MTYPE_ICMP` to the log filter and the warn filter. Refer to Debugging on page 1163 for detailed information about logging.
4.8.46  IP_SendPingEx()

Description
Sends a single ICMP echo request ("ping") to the specified host using the selected interface.

Prototype

```c
int IP_SendPingEx(U32 IFaceId, U32 FHost, char * pData, unsigned NumBytes, U16 SeqNum);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>FHost</td>
<td>4-byte IPv4 address in network endian byte order of the target.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer on the ping data, NULL if do not care.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of data to attach to ping request.</td>
</tr>
<tr>
<td>SeqNum</td>
<td>Ping sequence number.</td>
</tr>
</tbody>
</table>

Return value

- 0   OK
- < 0 Error

Additional information
If you call this function with activated logging, the ICMP reply or (in case of an error) the error message will be sent to stdout. To enable the output of ICMP status messages, add the message type IP_MTYPE_ICMP to the log filter and the warn filter. Refer to Debugging on page 1163 for detailed information about logging.
4.8.47 IP_SetIFaceConnectHook()

Description
Sets a hook for an interface that is executed when IP_Connect() is called.

Prototype
void IP_SetIFaceConnectHook(unsigned IFaceId, int (*pf)(unsigned IFaceId));

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pf</td>
<td>Hook that is called on IP_Connect().</td>
</tr>
</tbody>
</table>

Additional information
Typically for a pure Ethernet interface this functionality is not needed. Typically it is used with dial-up interfaces or interfaces that need more configurations to be set by the application to work.
### 4.8.48 IP_SetIFaceDisconnectHook()

**Description**

Sets a hook for an interface that is executed when `IP_Disconnect()` is called.

**Prototype**

```c
void IP_SetIFaceDisconnectHook(unsigned IFaceId, int (*pf)(unsigned IFaceId));
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pf</td>
<td>Hook that is called on <code>IP_Disconnect()</code></td>
</tr>
</tbody>
</table>

**Additional information**

Typically for a pure Ethernet interface this functionality is not needed. Typically it is used with dial-up interfaces or interfaces that need more configurations to be set by the application to work.
4.8.49 IP_SetOnPacketFreeCallback()

Description
This function sets a callback to be executed once the packet has been freed.

Prototype

```c
void  IP_SetOnPacketFreeCallback
    (IP_PACKET *  pPacket,
     void         (  * pfOnFreeCB )( IP_PACKET *  pPacketCB , void *  pContextCB ),
     void       *  pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer on the packet.</td>
</tr>
<tr>
<td>pfOnFreeCB</td>
<td>Callback that is notified on a packet free.</td>
</tr>
<tr>
<td>pContext</td>
<td>Application context that will be passed to the callback once the packet gets freed.</td>
</tr>
</tbody>
</table>
4.8.50   IP_SetPacketToS()

Description
Sets the value of the ToS byte in the IP header of a packet to be sent via the zero-copy API.

Prototype

```c
void IP_SetPacketToS(IP_PACKET * pPacket, U8 ToS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to packet buffer.</td>
</tr>
<tr>
<td>ToS</td>
<td>ToS byte to use in packet when being sent.</td>
</tr>
</tbody>
</table>
4.8.51   IP_SetRxHook()

Description
Sets a hook function which will be called if target receives a packet.

Prototype

```c
void IP_SetRxHook(IP_RX_HOOK * pfRxHook);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfRxHook</td>
<td>Pointer to the callback function of type IP_RX_HOOK.</td>
</tr>
</tbody>
</table>

Additional information

The return value of the callback function is relevant for the further processing of the packet. A return value of 0 indicates that the stack has to process the packet after the callback has returned. A return value of >0 indicates that the packet will be freed directly after the callback has returned.

The prototype for the callback function is defined as follows:

```c
typedef int (IP_RX_HOOK)(IP_PACKET * pPacket);
```

Example

Refer to `IP_ICMP_SetRxHook` on page 224 for an example.
4.8.52  IP_SetMicrosecondsCallback()

Description
Sets a callback that is used to get a timestamp in microseconds.

Prototype

```c
void IP_SetMicrosecondsCallback(U64 (*pfGetTime_us)());
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGetTime_us</td>
<td>The callback to set.</td>
</tr>
</tbody>
</table>

Example

```c
IP_SetMicrosecondsCallback(OS_GetTime_us64);
```
4.9 Stack internal functions, variables and data-structures

embOS/IP internal functions, variables and data-structures are not explained here as they are in no way required to use embOS/IP. Your application should not rely on any of the internal elements, as only the documented API functions are guaranteed to remain unchanged in future versions of embOS/IP. The following data-structures are meant for public usage together with the documented API.
### 4.9.1 Structure BSP_IP_INSTALL_ISR_PARA

**Description**

Used to pass parameters for installing an ISR handler between driver and hardware specific callback.

**Prototype**

```c
typedef struct {
    void (*pfISR)(void);
    int ISRIndex;
    int Prio;
} BSP_IP_INSTALL_ISR_PARA;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfISR</td>
<td>Interrupt handler to register.</td>
</tr>
<tr>
<td>ISRIndex</td>
<td>Interrupt index given by the driver as reference. The index might differ from hardware to hardware.</td>
</tr>
<tr>
<td>Prio</td>
<td>Interrupt priority given by the driver as reference. Override this with a priority that best fits your system.</td>
</tr>
</tbody>
</table>
4.9.2 Structure BSP_IP_API

Description
Used to set callbacks for a driver to call hardware specific functions that can not be handled in a generic way by the driver itself.

Prototype

```c
typedef struct {
    void (*pfInit) (unsigned IFaceId);
    void (*pfDeInit) (unsigned IFaceId);
    void (*pfInstallISR) (unsigned IFaceId, BSP_IP_INSTALL_ISR_PARA * pPara);
} BSP_IP_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfInit</td>
<td>Initializes port pins and clocks for Ethernet. Can be NULL.</td>
</tr>
<tr>
<td>pfDeInit</td>
<td>De-initializes port pins and clocks for Ethernet. Can be NULL.</td>
</tr>
<tr>
<td>pfInstallISR</td>
<td>Installs driver interrupt handler. Can be NULL. For further information regarding BSP_IP_INSTALL_ISR_PARA please refer to Structure BSP_IP_INSTALL_ISR_PARA on page 251.</td>
</tr>
</tbody>
</table>

Additional information
For further information about how this structure is used please refer to `IP_BSP_SetAPI` on page 89.
4.9.3 Structure SEGGER_CACHE_CONFIG

Description
Used to pass cache configuration and callback function pointers to the stack.

Prototype

```c
typedef struct {
    int CacheLineSize;
    void (*pfDMB)        (void);
    void (*pfClean)      (void *p, unsigned NumBytes);
    void (*pfInvalidate)(void *p, unsigned NumBytes);
} SEGGER_CACHE_CONFIG;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
</table>
| CacheLineSize | Length of one cache line of the CPU.  
                = 0: No Cache.  
                > 0: Cache line size in bytes.  
                Most Systems such as ARM9 use a 32 bytes cache line size. |
| pfDMB         | Pointer to a callback function that executes a DMB (Data Memory Barrier) instruction to make sure all memory operations are completed. Can be NULL. |
| pfClean       | Pointer to a callback function that executes a clean operation on cached memory. Can be NULL. |
| pfInvalidate  | Pointer to a callback function that executes a clean operation on cached memory. Can be NULL. |

Additional information
For further information about how this structure is used please refer to IP_CACHE_SetConfig on page 97.
4.9.4 IP_STATS_IFACE

Description
Used to access the whole structure that can be accessed individually using the IP_STATS_* functions. Primary usage for these information is utilizing them for SNMP statistics, therefore their SNMP usage is explained.

Prototype

```c
typedef struct {
    U32 LastLinkStateChange;
    U32 RxBytesCnt;
    U32 RxUnicastCnt;
    U32 RxNotUnicastCnt;
    U32 RxDiscardCnt;
    U32 RxErrCnt;
    U32 RxUnknownProtoCnt;
    U32 TxBytesCnt;
    U32 TxUnicastCnt;
    U32 TxNotUnicastCnt;
    U32 TxDiscardCnt;
    U32 TxErrCnt;
} IP_STATS_IFACE;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description (SNMP usage)</th>
</tr>
</thead>
<tbody>
<tr>
<td>LastLinkStateChange</td>
<td>SNMP: ifLastChange [TimeTicks]. Needs to be converted into in 1/100 seconds since SNMP epoch.</td>
</tr>
<tr>
<td>RxBytesCnt</td>
<td>SNMP: ifInOctets [Counter].</td>
</tr>
<tr>
<td>RxUnicastCnt</td>
<td>SNMP: ifInUcastPkts [Counter].</td>
</tr>
<tr>
<td>RxNotUnicastCnt</td>
<td>SNMP: ifInNUcastPkts [Counter].</td>
</tr>
<tr>
<td>RxDiscardCnt</td>
<td>SNMP: ifIndiscards [Counter].</td>
</tr>
<tr>
<td>RxErrCnt</td>
<td>SNMP: ifInErrors [Counter].</td>
</tr>
<tr>
<td>RxUnknownProtoCnt</td>
<td>SNMP: ifInUnknownProtos [Counter].</td>
</tr>
<tr>
<td>TxBytesCnt</td>
<td>SNMP: ifOutOctets [Counter].</td>
</tr>
<tr>
<td>TxUnicastCnt</td>
<td>SNMP: ifOutUcastPkts [Counter].</td>
</tr>
<tr>
<td>TxNotUnicastCnt</td>
<td>SNMP: ifOutNUcastPkts [Counter].</td>
</tr>
<tr>
<td>TxDiscardCnt</td>
<td>SNMP: ifOutDiscards [Counter].</td>
</tr>
<tr>
<td>TxErrCnt</td>
<td>SNMP: ifOutErrors [Counter].</td>
</tr>
</tbody>
</table>
Chapter 5

Socket interface

The embOS/IP socket API is almost compatible to the Berkeley socket interface. The Berkeley
socket interface is the de facto standard for socket communication. embOS/ IP specific functions
allow an easier or even extended usage of some socket operations. All API functions are described
in this chapter.
## 5.1 API functions

The table below lists the available socket API functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Generic socket interface functions</strong></td>
<td></td>
</tr>
<tr>
<td>accept()</td>
<td>Accepts an incoming attempt on a socket.</td>
</tr>
<tr>
<td>bind()</td>
<td>Assigns a name (port) to an unnamed socket.</td>
</tr>
<tr>
<td>closesocket()</td>
<td>Closes a socket.</td>
</tr>
<tr>
<td>connect()</td>
<td>Establishes a connection to a socket.</td>
</tr>
<tr>
<td>gethostbyname()</td>
<td>Resolve a host name into an IP address.</td>
</tr>
<tr>
<td>getpeername()</td>
<td>Fills the passed structure sockaddr with the IP addressing information of the connected host.</td>
</tr>
<tr>
<td>getsockname()</td>
<td>Returns the current address to which the socket is bound in the buffer pointed to by pAddr.</td>
</tr>
<tr>
<td>getsockopt()</td>
<td>Returns the options associated with a socket.</td>
</tr>
<tr>
<td>listen()</td>
<td>Prepares the socket to accept connections.</td>
</tr>
<tr>
<td>recv()</td>
<td>Receives data from a connected socket.</td>
</tr>
<tr>
<td>recvfrom()</td>
<td>Receives a datagram and stores the source address.</td>
</tr>
<tr>
<td>select()</td>
<td>Implement a UNIX-like socket select call.</td>
</tr>
<tr>
<td>send()</td>
<td>Hands data to the stack in order to send it to a connected socket.</td>
</tr>
<tr>
<td>sendto()</td>
<td>Hands data to the stack in order to send it to a specified address on a socket.</td>
</tr>
<tr>
<td>setsockopt()</td>
<td>Configures some options for the socket.</td>
</tr>
<tr>
<td>shutdown()</td>
<td>Stops specific activities on a socket.</td>
</tr>
<tr>
<td>socket()</td>
<td>Creates a socket.</td>
</tr>
<tr>
<td><strong>embOS/IP specific socket interface functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_RAW_AddPacketToSocket()</td>
<td>Adds a packet and its data to a RAW socket (buffer).</td>
</tr>
<tr>
<td>IP_SOCKET_GetAddrFam()</td>
<td>Returns the IP version of a socket (IPv4 or IPv6).</td>
</tr>
<tr>
<td>IP_SOCKET_GetLocalPort()</td>
<td>Returns the local port of a socket.</td>
</tr>
<tr>
<td>IP_SOCKET_CloseAll()</td>
<td>Closes all socket handles that are open.</td>
</tr>
<tr>
<td>IP_SOCK_recvfrom_ts()</td>
<td>Receives a datagram and stores the source address and timestamp.</td>
</tr>
<tr>
<td>IP_TCP_Accept()</td>
<td>Registers a callback that will be executed upon a new client.</td>
</tr>
<tr>
<td><strong>Set management functions</strong></td>
<td></td>
</tr>

</tbody>
</table>
5.1.1 accept()

Description
Accepts an incoming attempt on a socket.

Prototype

```c
int accept(int Socket,
            sockaddr * pSockAddr,
            int * pAddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSockAddr</td>
<td>An optional pointer to a buffer where the address of the connecting entity is stored. The format of the address depends on the defined address family which was defined when the socket was created.</td>
</tr>
<tr>
<td>pAddrLen</td>
<td>As input an optional pointer to a variable with the maximum length of socket address that can be stored. As output an optional pointer to an integer where the length of the received address is stored. Just like the format of the address, the length of the address depends on the defined address family.</td>
</tr>
</tbody>
</table>

Return value

≥ 0  Socket handle of the socket on which the actual connection is made.
= -1  Error.

Additional information

This call is used with connection-based socket types, currently with SOCK_STREAM. Refer to `socket()` for more information about the different socket types.

Before calling `accept()`, the used socket `Socket` has to be bound to an address with `bind()` and should be listening for connections after calling `listen()`. `accept()` extracts the first connection on the queue of pending connections, creates a new socket with the same properties of `Socket` and allocates a new file descriptor for the socket. If no pending connections are present on the queue, and the socket is not marked as non-blocking, `accept()` blocks the caller until a connection is present. If the socket is marked non-blocking and no pending connections are present on the queue, `accept()` returns and reports an error. The accepted socket is used to read and write data to and from the socket which is connected to this one; it is not used to accept more connections. The original socket `Socket` remains open for accepting further connections.

The argument `pSockAddr` is a result parameter that is filled in with the address of the connecting entity as known to the communications layer. The exact format of the `pSockAddr` parameter is determined by the domain in which the communication is occurring. The `pAddrLen` is a value-result parameter. It should initially contain the amount of space pointed to by `pSockAddr`.

Example

The following sample can be used to retrieve information about the accepted client:

```c
struct sockaddr_in Client;
...
struct sockaddr_in Addr;
int AddrLen;
```
AddrLen = sizeof(Addr);
if ( (hSock = accept(hSockListen, (struct sockaddr *)&Addr, &AddrLen)) ==
    SOCKET_ERROR) {
    continue;  // Error
}
...

For example the peer IP address can then be retrieved in network endianess from Addr.sin_addr.s_addr.
5.1.2 bind()

Description
Assigns a name (port) to an unnamed socket.

Prototype

```c
int bind(int Socket, sockaddr * pSockAddr, int AddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSockAddr</td>
<td>A pointer to a buffer where the address of the connecting entity is stored.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>The length of the address.</td>
</tr>
</tbody>
</table>

Return value

0  Success.
-1  Error.

Additional information

When a socket is created with `socket()` it exists in a name space (address family) but has no name assigned. `bind()` is used on an unconnected socket before subsequent calls to the `connect()` or `listen()` functions. `bind()` assigns the name pointed to by `pSockAddr` to the socket.
5.1.3 closesocket()

Description
Closes a socket.

Prototype
int closesocket(int Socket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
</tbody>
</table>

Return value
0 On success.
-1 On failure.

Additional information
closesocket() closes a connection on the socket associated with Socket and the socket descriptor associated with Socket will be returned to the free socket descriptor pool. Once a socket is closed, no further socket calls should be made with it.

If the socket promises reliable delivery of data and SO_LINGER is set, the system will block the caller on the closesocket() attempt until it is able to transmit the data or until it decides it is unable to deliver the information (a timeout period, termed the linger interval, is specified in the setsockopt() call when SO_LINGER is requested). If SO_LINGER is disabled and a closesocket() is issued, the system will process the close in a manner that allows the caller to continue as quickly as possible. If SO_LINGER is enabled with a timeout period of ‘0’ and a closesocket() is issued, the system will perform a hard close.

Example

```c
/* *************************************************************************/
*/
/* _CloseSocketGracefully() */
/* Function description */
/* Wrapper for closesocket() with linger enabled to verify a graceful */
/* disconnect. */
*/
static int _CloseSocketGracefully(long pConnectionInfo) {
    struct linger Linger;
    Linger.l_onoff = 1; // Enable linger for this socket.
    Linger.l_linger = 1; // Linger timeout in seconds
    setsockopt(hSocket, SOL_SOCKET, SO_LINGER, &Linger, sizeof(Linger));
    return closesocket(hSocket);
}

/* *************************************************************************/
*/
/* _CloseSocketHard() */
/* Function description */
/* Wrapper for closesocket() with linger option enabled to perform a hard */
/* close. */
*/
static int _CloseSocketHard(long hSocket) {
    struct linger Linger;
    Linger.l_onoff = 1; // Enable linger for this socket.
    Linger.l_linger = 0; // Linger timeout in seconds
    setsockopt(hSocket, SOL_SOCKET, SO_LINGER, &Linger, sizeof(Linger));
```
```c
return closesocket(hSocket);
}
```
5.1.4 connect()

Description
Establishes a connection to a socket.

Prototype

```c
int connect(int Socket, sockaddr * pSockAddr, int AddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSockAddr</td>
<td>A pointer to a buffer where the address of the connecting entity is stored.</td>
</tr>
<tr>
<td></td>
<td>The format of the address depends on the defined address family which was</td>
</tr>
<tr>
<td></td>
<td>defined when the socket was created.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>A pointer to an integer where the length of the received address is stored.</td>
</tr>
<tr>
<td></td>
<td>Just like the format of the address, the length of the address depends on</td>
</tr>
<tr>
<td></td>
<td>the defined address family.</td>
</tr>
</tbody>
</table>

Return value

0   On success.
-1  On failure.

Additional information

If `Socket` is of type `SOCK_DGRAM` or `SOCK_RAW`, then this call specifies the peer with which the socket is to be associated. `pAddr` defines the address to which datagrams are sent and the only address from which datagrams are received. To enable RAW socket support in the IP stack it is mandatory to call `IP_RAW_Add()` during initialization of the stack.

If `Socket` is of type `SOCK_STREAM`, then this call attempts to make a connection to another socket. The other socket is specified by `pSockAddr` which is an address in the communications space of the socket. Each communications space interprets the `pSockAddr` parameter in its own way.

Generally, stream sockets may successfully `connect()` only once; datagram sockets may use `connect()` multiple times to change their association. Datagram sockets may dissolve the association by connecting to an invalid address, such as a NULL address.

If a `connect` is in progress and the socket is blocking, the `connect` call waits until `connect`ed or an error to happen. If the socket is non-blocking (refer to `setsockopt()` for more information), 0 is returned.

You can use the `getsockopt()` function to determine the status of the `connect` attempt.

The timeout for a `connect` attempt can be configured via the Init parameter of `IP_TCP_SetConnKeepaliveOpt()`.

Example

```c
#define SERVER_PORT             1234
#define SERVER_IP_ADDR          0xC0A80101 // 192.168.1.1

/*********************************************************************
*       _TCPClientTask
* Function description
```
* Creates a connection to a given IP address, TCP port.
*/
static void _TCPClientTask(void) {
    int TCPSockID;
    struct sockaddr_in ServerAddr;
    int ConnectStatus;

    // Wait until link is up. This can take 2-3 seconds if PHY has been reset.
    while (IP_GetCurrentLinkSpeed() == 0) {
        OS_Delay(100);
    }

    while(1) {
        TCPSockID = socket(AF_INET, SOCK_STREAM, 0);  // Open socket
        if (TCPSockID < 0) {  // Error, Could not get socket
            while (1) {
                OS_Delay(20);
            }
        } else {
            // Connect to server
            ServerAddr.sin_family = AF_INET;
            ServerAddr.sin_port = htons(SERVER_PORT);
            ServerAddr.sin_addr.s_addr = htonl(SERVER_IP_ADDR);
            ConnectStatus = connect(TCPSockID,
                (struct sockaddr *)&ServerAddr,
                sizeof(struct sockaddr_in));

            if (ConnectStatus == 0) {
                // Do something...
            } else {
                closesocket(TCPSockID);
            }
            OS_Delay(50);
        }
    }
}
5.1.5 gethostbyname()

Description
Resolve a host name into an IP address.

Prototype
gethostbyname(const char * sName);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Host name to resolve.</td>
</tr>
</tbody>
</table>

Return value
OK: Pointer to a hostent structure Error: NULL if not successful.

Additional information
The function is called with a string containing the host name to be resolved as a fully-qualified domain name (for example, myhost.mydomain.com).

Example

```c
static void _DNSClient() {
    struct hostent *pHostEnt;
    char **ps;
    char **ppAddr;
    // Wait until link is up.
    // while (IP_IFaceIsReady() == 0) {
    OS_Delay(100);
    }
    while(1) {
        pHostEnt = gethostbyname("www.segger.com");
        if (pHostEnt == NULL) {
            printf("Could not resolve host addr.
        break;
        }
        printf("h_name: %s\n", pHostEnt->h_name);
        // Show aliases
        // ps = pHostEnt->h_aliases;
        for (;) {
            char * s;
            s = *ps++;
            if (s == NULL) {
                break;
            }
            printf("h_aliases: %s\n", s);
        }
        // Show IP addresses
        // ppAddr = pHostEnt->h_addr_list;
        for (;) {
            U32 IPAddr;
            char * pAddr;
            char ac[16];
            pAddr = *ppAddr++;
            if (pAddr == NULL) {
                break;
            }
        }
    }
}
```
Note

gethostbyname() is not thread safe and should therefore only be used where absolutely necessary. If possible use the thread safe function IP_ResolveHost() instead.
5.1.6  getpeername()

Description
Fills the passed structure sockaddr with the IP addressing information of the connected host.

Prototype

```c
int getpeername(int Socket,
                sockaddr * pSockAddr,
                int * pAddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSockAddr</td>
<td>A pointer to a structure of type sockaddr in which the IP address information of the connected host should be stored.</td>
</tr>
<tr>
<td>pAddrLen</td>
<td>Max. size of address to return without exceeding the output buffer.</td>
</tr>
</tbody>
</table>

Return value

0  Success.
-1  Error.

Additional information

Refer to Structure sockaddr on page 294 for detailed information about the structure sockaddr.

Example

The following sample can be used to retrieve information about the peer host from an existing connection:

```c
struct sockaddr_in Client;
int i;
...
if ((hSock = accept(hSockListen, &Addr, &AddrLen)) == SOCKET_ERROR) {
    continue;  // Error
}
i = sizeof(Client);
getpeername(hSock, (struct sockaddr *)&Client, &i);
...
```

For example the peer IP address can then be retrieved in network endianess from Client.sin_addr.s_addr.
5.1.7 getsockname()

Description
Returns the current address to which the socket is bound in the buffer pointed to by `pAddr`.

Prototype
```c
int getsockname(int Socket, sockaddr * pSockAddr, int * pAddrLen);
```

Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSockAddr</td>
<td>A pointer to a structure of type sockaddr in which the IP address information of the connected host should be stored.</td>
</tr>
<tr>
<td>pAddrLen</td>
<td>Max. size of address to return without exceeding the output buffer.</td>
</tr>
</tbody>
</table>

Return value
0 Success.
-1 Error.

Additional information
Refer to `Structure sockaddr` on page 294 for detailed information about the structure sockaddr.
5.1.8 getsockopt()

Description
Returns the options associated with a socket.

Prototype

```c
int getsockopt(int Socket,
               int Level,
               int Option,
               void * pVal,
               int ValLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>Level</td>
<td>Compatibility parameter for setsockopt() and getsockopt(). Use symbol SOL_SOCKET.</td>
</tr>
<tr>
<td>Option</td>
<td>The socket option which should be retrieved.</td>
</tr>
<tr>
<td>pVal</td>
<td>A pointer to the buffer in which the value of the requested option should be stored.</td>
</tr>
<tr>
<td>ValLen</td>
<td>The size of the data buffer.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>-1</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Valid values for parameter Option

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard option flags.</td>
<td></td>
</tr>
<tr>
<td>SO_ACCEPTCONN</td>
<td>Indicates that socket is in listen mode.</td>
</tr>
<tr>
<td>SO_DONTROUTE</td>
<td>Indicates that outgoing messages must bypass the standard routing facilities. Instead, messages are directed to the appropriate network interface according to the network portion of the destination address.</td>
</tr>
<tr>
<td>SO_KEEPALIVE</td>
<td>Indicates that the periodic transmission of messages on a connected socket is enabled. If the connected party fails to respond to these messages, the connection is considered broken.</td>
</tr>
<tr>
<td>SO_LINGER</td>
<td>Indicates that linger on close is enabled.</td>
</tr>
<tr>
<td>SO_NOSLOWSTART</td>
<td>Indicates that suppress slow start on this socket is enabled.</td>
</tr>
<tr>
<td>SO_TIMESTAMP</td>
<td>Indicates that the TCP timestamp option is enabled.</td>
</tr>
<tr>
<td></td>
<td>embOS/IP socket options.</td>
</tr>
<tr>
<td>SO_ERROR</td>
<td>Stores the latest socket error in pVal and clears the error in socket structure.</td>
</tr>
<tr>
<td>SO_MYADDR</td>
<td>Stores the IP address of the used interface in pVal.</td>
</tr>
</tbody>
</table>
## Additional information

`getsockopt()` retrieves the current value for a socket option associated with a socket of any type, in any state, and stores the result in `pVal`. Options can exist at multiple protocol levels, but they are always present at the uppermost “socket” level. Options affect socket operations, such as the packet routing.

The value associated with the selected option is returned in the buffer `pVal`. The integer pointed to by `ValLen` should originally contain the size of this buffer; on return, it will be set to the size of the value returned. For `SO_LINGER`, this will be the size of a LINGER structure. For most other options, it will be the size of an integer.

The application is responsible for allocating any memory space pointed to directly or indirectly by any of the parameters it specified. If the option was never set with `setsockopt()`, then `getsockopt()` returns the default value for the option.

The option `SO_ERROR` returns 0 or the number of the socket error and clears the socket error. The following table lists the socket errors.

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_ERR_SEND_PENDING</td>
<td>1</td>
<td>Packet to send is not sent yet.</td>
</tr>
<tr>
<td>IP_ERR_MISC</td>
<td>-1</td>
<td>Miscellaneous errors that do not have a specific error code.</td>
</tr>
<tr>
<td>IP_ERR_TIMEDOUT</td>
<td>-2</td>
<td>Operation timed out.</td>
</tr>
<tr>
<td>IP_ERR_ISCONN</td>
<td>-3</td>
<td>Socket is already connected.</td>
</tr>
<tr>
<td>IP_ERR_OP_NOT_SUPP</td>
<td>-4</td>
<td>Operation not supported for selected socket.</td>
</tr>
<tr>
<td>IP_ERR_CONN_ABORTED</td>
<td>-5</td>
<td>Connection was aborted.</td>
</tr>
<tr>
<td>IP_ERR_WOULD_BLOCK</td>
<td>-6</td>
<td>Socket is in non-blocking state and the current operation would block the socket if not in non-blocking state.</td>
</tr>
<tr>
<td>IP_ERR_CONN_REFUSED</td>
<td>-7</td>
<td>Connection refused by peer.</td>
</tr>
<tr>
<td>IP_ERR_CONN_RESET</td>
<td>-8</td>
<td>Connection has been reset.</td>
</tr>
<tr>
<td>IP_ERR_NOT_CONN</td>
<td>-9</td>
<td>Socket is not connected.</td>
</tr>
<tr>
<td>IP_ERR_ALREADY</td>
<td>-10</td>
<td>Socket already is in the requested state.</td>
</tr>
<tr>
<td>IP_ERR_IN_VAL</td>
<td>-11</td>
<td>Passed value for configuration is not valid.</td>
</tr>
<tr>
<td>IP_ERR_MSG_SIZE</td>
<td>-12</td>
<td>Message is too big to send.</td>
</tr>
<tr>
<td>IP_ERR_PIPE</td>
<td>-13</td>
<td>Socket is not in the correct state for this operation.</td>
</tr>
<tr>
<td>IP_ERR_DEST_ADDR_REQ</td>
<td>-14</td>
<td>Destination addr. has not been specified.</td>
</tr>
<tr>
<td>Symbolic name</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IP_ERR_SHUTDOWN</td>
<td>-15</td>
<td>Connection has been closed as soon as all data has been received upon a FIN request.</td>
</tr>
<tr>
<td>IP_ERR_NO_PROTO_OPT</td>
<td>-16</td>
<td>Unknown socket option for <code>setsockopt()</code> or <code>getsockopt()</code>.</td>
</tr>
<tr>
<td>IP_ERR_NO_MEM</td>
<td>-18</td>
<td>Not enough memory in the memory pool.</td>
</tr>
<tr>
<td>IP_ERR_ADDR_NOT_AVAIL</td>
<td>-19</td>
<td>No known path to send to the specified addr.</td>
</tr>
<tr>
<td>IP_ERR_ADDR_IN_USE</td>
<td>-20</td>
<td><code>Socket</code> already has a connection to this addr. and port or is already bound to this addr.</td>
</tr>
<tr>
<td>IP_ERR_IN_PROGRESS</td>
<td>-22</td>
<td>Operation is still in progress.</td>
</tr>
<tr>
<td>IP_ERR_NO_BUF</td>
<td>-23</td>
<td>No internal buffer was available.</td>
</tr>
<tr>
<td>IP_ERR_NOT.SOCK</td>
<td>-24</td>
<td><code>Socket</code> has not been opened or has already been closed.</td>
</tr>
<tr>
<td>IP_ERR_FAULT</td>
<td>-25</td>
<td>Generic error for a failed operation.</td>
</tr>
<tr>
<td>IP_ERR_NET_UNREACH</td>
<td>-26</td>
<td>No path to the desired network available.</td>
</tr>
<tr>
<td>IP_ERR_PARAM</td>
<td>-27</td>
<td>Invalid parameter to function.</td>
</tr>
<tr>
<td>IP_ERR_LOGIC</td>
<td>-28</td>
<td>Logical error that should not have happened.</td>
</tr>
<tr>
<td>IP_ERR_NOMEM</td>
<td>-29</td>
<td>System error: No memory for requested operation.</td>
</tr>
<tr>
<td>IP_ERR_NOBUFFER</td>
<td>-30</td>
<td>System error: No internal buffer available for the requested operation.</td>
</tr>
<tr>
<td>IP_ERR_RESOURCE</td>
<td>-31</td>
<td>System error: Not enough free resources available for the requested operation.</td>
</tr>
<tr>
<td>IP_ERR_BAD_STATE</td>
<td>-32</td>
<td><code>Socket</code> is in an unexpected state.</td>
</tr>
<tr>
<td>IP_ERR_TIMEOUT</td>
<td>-33</td>
<td>Requested operation timed out.</td>
</tr>
<tr>
<td>IP_ERR_NO_ROUTE</td>
<td>-36</td>
<td>Net error: Destination is unreachable.</td>
</tr>
<tr>
<td>IP_ERR_QUEUE_FULL</td>
<td>-37</td>
<td>No more packets can be queued for sending. Typically caused by packets waiting for an ARP response to be fulfilled.</td>
</tr>
</tbody>
</table>
5.1.9 listen()

Description
Prepares the socket to accept connections.

Prototype

```c
int listen(int Socket,
           int Backlog);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>Backlog</td>
<td>Backlog for incoming connections. Defines the maximum length of the queue of pending connections.</td>
</tr>
</tbody>
</table>

Return value

-1 Error.
0 Success.

Additional information

The `listen()` call applies only to sockets of type `SOCK_STREAM`. If a connection request arrives when the queue is full, the client will receive an error with an indication of ECONREFUSED.

Example

```c
/***************************************************************************/
/*
 */
/*   _ListenAtTcpAddr
*/
/*   Function description
 */
/*   Starts listening at the given TCP port.
 */
static int _ListenAtTcpAddr(U16 Port) {
    int Sock;
    struct sockaddr_in Addr;

    Sock = socket(AF_INET, SOCK_STREAM, 0);
    memset(&Addr, 0, sizeof(Addr));
    Addr.sin_family = AF_INET;
    Addr.sin_port = htons(Port);
    Addr.sin_addr.s_addr = INADDR_ANY;
    bind(Sock, (struct sockaddr *)&Addr, sizeof(Addr));
    listen(Sock, 1);
    return Sock;
}
```
5.1.10 recv()

Description
Receives data from a connected socket.

Prototype

```c
int recv(int Socket,
         char * pData,
         int NumBytes,
         int Flag);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Handle on the socket.</td>
</tr>
<tr>
<td>pData</td>
<td>A pointer to a buffer for incoming data.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes of the buffer.</td>
</tr>
<tr>
<td>Flag</td>
<td>OR-combination of flags (MSG_PEEK).</td>
</tr>
</tbody>
</table>

Return value

- = -1   Error occurred.
- = 0    Connection was gracefully closed.
- > 0    Number of bytes received.

Additional information

If a message is too long to fit in the supplied buffer, excess bytes may be discarded depending on the type of socket the message is received from. Refer to `socket()` for more information about the different types of sockets.

You can only use the `recv()` function on a connected socket. To receive data on a socket, whether it is in a connected state or not refer to `recvfrom()`. If no messages are available at the socket and the socket is blocking, the receive call waits for a message to arrive. If the socket is non-blocking (refer to `setsockopt()` for more information), 1 is returned.

You can use the `select()` function to determine when more data arrives.

Valid values for parameter Flag

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG_PEEK</td>
<td>&quot;Peek&quot; at the data present on the socket; the data are returned, but not consumed, so that a subsequent receive operation will see the same data.</td>
</tr>
</tbody>
</table>
5.1.11 recvfrom()

Description
Receives a datagram and stores the source address.

Prototype

```c
int recvfrom(int Socket,
             char * pData,
             int NumBytes,
             int Flag,
             sockaddr * pFrom,
             int * pFromLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Handle on the socket.</td>
</tr>
<tr>
<td>pData</td>
<td>A pointer to a buffer for incoming data.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes of the buffer pointed by pData.</td>
</tr>
<tr>
<td>Flag</td>
<td>OR-combination of flags (MSG_PEEK).</td>
</tr>
<tr>
<td>pFrom</td>
<td>An optional pointer to a buffer where the address of the con-</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>socket was created. Can be NULL.</td>
</tr>
<tr>
<td>pFromLen</td>
<td>An optional pointer to an integer where the length of the re-</td>
</tr>
<tr>
<td></td>
<td>ceived address is stored. Just like the format of the address,</td>
</tr>
<tr>
<td></td>
<td>the length of the address depends on the defined address</td>
</tr>
<tr>
<td></td>
<td>family.</td>
</tr>
</tbody>
</table>

Return value

= -1      Error occurred.
≥ 0       Number of bytes received.

Additional information

If pFrom is not a NULL pointer, the source address of the message is filled in. pFromLen is a value-result parameter, initialized to the size of the buffer associated with pFrom, and modified on return to indicate the actual size of the address stored there.

If a message is too long to fit in the supplied buffer, excess bytes may be discarded depending on the type of socket the message is received from. Refer to socket() for more information about the different types of sockets.

If no messages are available at the socket and the socket is blocking, the receive call waits for a message to arrive. If the socket is non-blocking (refer to setsockopt() for more information), 1 is returned.

You can use the select() function to determine when more data arrives.

Valid values for parameter Flag

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG_PEEK</td>
<td>“Peek” at the data present on the socket; the data are returned, but not consumed, so that a subsequent receive operation will see the same data.</td>
</tr>
</tbody>
</table>
5.1.12 select()

Description

Implement a UNIX-like socket select call. Causes the calling process to block waiting for activity on any of a list of sockets. Arrays of socket descriptions are passed for read, write, and exception event. Any of these may be NULL of the event is not of interest. A timeout is also passed, which given in ticks (typically 1000 ticks per second). Returns number of sockets which had an event occur.

Prototype

```c
int select(IP_fd_set * readfds,
        IP_fd_set * writefds,
        IP_fd_set * exceptfds,
        I32         tv);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>readfds</td>
<td>Read file descriptor set.</td>
</tr>
<tr>
<td>writefds</td>
<td>Write file descriptor set.</td>
</tr>
<tr>
<td>exceptfds</td>
<td>Exception file descriptor set.</td>
</tr>
<tr>
<td>tv</td>
<td>Minimum interval that select() should block waiting for a file descriptor to become ready. -1 for no timeout.</td>
</tr>
</tbody>
</table>

Return value

-1  Error occurred.
= 0  Timeout.
> 0  Number of file descriptors contained in the three descriptor sets.

Additional information

On return, select() replaces the given descriptor sets with subsets consisting of those descriptors that are ready for the requested operation. The total number of ready descriptors in all the sets is returned. Any of readfds, writefds, and exceptfds may be given as NULL pointers if no descriptors are of interest. Selecting true for reading on a socket descriptor upon which a listen() call has been performed indicates that a subsequent accept() call on that descriptor will not block.

In the standard Berkeley UNIX Sockets API, the descriptor sets are stored as bit fields in arrays of integers. This works in the UNIX environment because under UNIX socket descriptors are file system descriptors which are guaranteed to be small integers that can be used as indexes into the bit fields. In embOS/IP, socket descriptors are pointers and thus a bit field representation of the descriptor sets is not feasible. Because of this, the embOS/IP API differs from the Berkeley standard in that the descriptor sets are represented as instances of the following structure:

```c
typedef struct IP_FD_SET {
    unsigned fd_count;           // The select socket array manager
    long fd_array[FD_SETSIZE];   // how many are SET?
    } IP_fd_set;
```

Instead of a socket descriptor being represented in a descriptor set via an indexed bit, an embOS/IP socket descriptor is represented in a descriptor set by its presence in the fd_array field of the associated IP_fd_set structure. Despite this non-standard representation of the descriptor sets themselves, the following standard entry points are provided for manipulating such descriptor sets: IP_FD_ZERO(&fdset) initializes a descriptor set fdset to the null set. IP_FD_SET(fd, &fdset) includes a particular descriptor, fd, in fdset. IP_FD_CLR(fd, &fdset) removes fd from fdset. IP_FD_ISSET(fd, &fdset) is nonzero
if `fd` is a member of `fdset`, zero otherwise. These entry points behave according to the standard Berkeley semantics.

You should be aware that the value of `FD_SETSIZE` defines the maximum number of descriptors that can be represented in a single descriptor set. The default value of `FD_SETSIZE` is 12. This value can be increased in the source code version of embOS/IP to accommodate a larger maximum number of descriptors at the cost of increased processor stack usage.

Another difference between the Berkeley and embOS/IP `select()` calls is the representation of the timeout parameter. Under Berkeley Sockets, the timeout parameter is represented by a pointer to a structure. Under embOS/IP sockets, a timeout is specified by the `tv` parameter, which defines the maximum number of milliseconds that should elapse before the call to `select()` returns. A `tv` parameter equal to 0 implies that `select()` should return immediately (effectively a poll of the sockets in the descriptor sets). A `tv` parameter equal to -1 implies that `select()` blocks forever unless one of its descriptors becomes ready.

The final difference between the Berkeley and embOS/IP versions of `select()` is the absence in the embOS/IP version of the Berkeley width parameter. The width parameter is of use only when descriptor sets are represented as bit arrays and was thus deleted in the embOS/IP implementation.

Note:
Under rare circumstances, `select()` may indicate that a descriptor is ready for writing when in fact an attempt to write would block. This can happen if system resources necessary for a write are exhausted or otherwise unavailable. If an application deems it critical that writes to a file descriptor not block, it should set the descriptor for non-blocking I/O. Refer to `setsockopt` on page 280 for detailed information.

Example

```c
static void _Client() {
  long                Socket;
  struct sockaddr_in Addr;
  IP_fd_set          readfds;
  char                RecvBuffer[1472]
  int                 r;

  while (IP_IFaceIsReady() == 0) {
    OS_Delay(100);
  }

  Restart:
  Socket = socket(AF_INET, SOCK_DGRAM, 0); // Open socket
  Addr.sin_family = AF_INET;
  Addr.sin_port = htons(2222);
  Addr.sin_addr.s_addr = INADDR_ANY;
  r = bind(Socket, (struct sockaddr *)&Addr, sizeof(Addr));
  if (r == -1){
    socketclose(Socket);
    OS_Delay(1000);
    goto Restart;
  }

  while(1) {
    IP_FD_ZERO(&readfds);
    IP_FD_SET(Socket, &readfds); // Add descriptor to the set
    r = select(&readfds, NULL, NULL, 5000); // Check for activity.
    if (r <= 0) {
      continue;
    }
    // No socket activity or error detected
    if (IP_FD_ISSET(Socket, &readfds)) {
      IP_FD_CLR(Socket, &readfds); // Remove socket from set
      r = recvfrom(Socket, RecvBuffer, sizeof(RecvBuffer), 0, NULL, NULL);
      if (r == -1){
        socketclose(Socket)
    }
```
goto Restart;
}
}
OS_Delay(100);
5.1.13  send()

Description
Hands data to the stack in order to send it to a connected socket. The stack will copy the
data into the socket buffer. In blocking mode, the function returns when all data have been
accepted by the stack. If non blocking mode, the function returns immediately.

Prototype

```c
int send( int Socket,
          const char * pBuffer,
          int NumBytes,
          int Flags);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle to a connected socket</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to a buffer that contains data to send</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes to send from pBuffer</td>
</tr>
<tr>
<td>Flags</td>
<td>OR-combination of one or more of the valid values listed in the table below.</td>
</tr>
</tbody>
</table>

Return value

< 0  Error (SOCKET_ERROR).
≥ 0  OK, Number of bytes accepted by the stack and ready to be sent. Note: In
     blocking mode this can only be the full number of bytes, since the function
     would otherwise block.

Additional information

send() may be used only when the socket is in a connected state. Refer to sendto() for
information about sending data to a non-connected socket.

If no messages space is available at the socket to hold the message to be transmitted, then
send() normally blocks, unless the socket has been placed in non-blocking I/O mode.

MSG_DONTROUTE is usually used only by diagnostic or routing programs.

Valid values for parameter Flags

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG_DONTROUTE</td>
<td>Specifies that the data should not be subject to routing.</td>
</tr>
</tbody>
</table>
5.1.14  sendto()

Description

Hands data to the stack in order to send it to a specified address on a socket. The stack will copy the data into the socket buffer. In blocking mode, the function returns when all data have been accepted by the stack. If non blocking mode, the function returns immediately.

Prototype

```c
int sendto(       int         Socket ,
                const  char      *  pBuffer ,
                int         NumBytes ,
                int         Flags ,
                sockaddr *  pDestAddr ,
                int         NumBytesAddr );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to a buffer that contains data to send</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes to send from pBuffer</td>
</tr>
<tr>
<td>Flags</td>
<td>Ignored at the moment</td>
</tr>
<tr>
<td>pDestAddr</td>
<td>Pointer to a buffer containing the destination address</td>
</tr>
<tr>
<td>NumBytesAddr</td>
<td>Length of the address stored at pDestAddr in bytes</td>
</tr>
</tbody>
</table>

Return value

- < 0  Error (SOCKET_ERROR).
- ≥ 0  OK, Number of bytes accepted by the stack and ready to be sent. Note: In blocking mode this can only be the full number of bytes, since the function would otherwise block.

Additional information

In contrast to send(), sendto() can be used at any time. The connection state is in which case the address of the target is given by the pDestAddr parameter.

Valid values for parameter Flags

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSG_DONTROUTE</td>
<td>Specifies that the data should not be subject to routing.</td>
</tr>
</tbody>
</table>
5.1.15 setsockopt()

Description
Configures some options for the socket.

Prototype

```c
int setsockopt(int Socket,
               int Level,
               int Name,
               void * pVal,
               int ValLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Socket</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>Level</td>
<td>Level at which the option should be interpreted (SOL_SOCKET for example).</td>
</tr>
<tr>
<td>Name</td>
<td>Option enum.</td>
</tr>
<tr>
<td>pVal</td>
<td>Pointer on the value for the given option.</td>
</tr>
<tr>
<td>ValLen</td>
<td>Length of the data pointed by pVal.</td>
</tr>
</tbody>
</table>

Return value

0        Success.
-1       Error.

Valid values for parameter Option

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO_DONTROUTE</td>
<td>Outgoing messages should bypass the standard routing facilities. Instead, messages are directed to the appropriate network interface according to the network portion of the destination address. By default, this socket option is disabled.</td>
</tr>
<tr>
<td>SO_KEEPALIVE</td>
<td>Enable periodic transmission of messages on a connected socket. If the connected party fails to respond to these messages, the connection is considered broken. By default, this socket option is enabled. For keepalive behavior configuration please refer to IP_TCP_SetConnKeepaliveOpt on page 140.</td>
</tr>
<tr>
<td>SO_LINGER</td>
<td>Controls the action taken when unsent messages are queued on a socket and a closesocket() is performed. Refer to closesocket on page 261 for detailed information about the linger option. By default, this socket option is disabled.</td>
</tr>
<tr>
<td>SO_TIMESTAMP</td>
<td>Enable the TCP timestamp option. By default, this socket option is disabled.</td>
</tr>
</tbody>
</table>

embOS/IP socket options.
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SO_CALLBACK</td>
<td>Sets zero-copy callback routine. Refer to <em>TCP zero-copy interface</em> on page 299 for detailed information.</td>
</tr>
<tr>
<td>SO_RCVTIMEO</td>
<td>Sets a timeout for <code>recv()</code> in ms like in Windows. This changes the behavior of <code>recv()</code>. <code>recv()</code> is by default a blocking function which only returns if data has been received. If a timeout is set <code>recv()</code> will return in case of data reception or timeout. By default, this socket option is disabled.</td>
</tr>
<tr>
<td>SO_NONBLOCK</td>
<td>Sets socket blocking status. Allows the caller to specify blocking or non-blocking IO that works the same as the other Boolean socket options. <code>pVal</code> points to an integer value which will contain a non-zero value to set non-blocking IO or a 0 value to reset non-blocking IO. By default, this socket option is disabled.</td>
</tr>
<tr>
<td>IP_HDRINCL</td>
<td>Configures if the IP header has to be included by the user or if the IP header is generated by the stack.</td>
</tr>
</tbody>
</table>

**Example**

```c
void _EnableKeepAlive(long sock) {
    int v = 1;
    setsockopt(sock, SOL_SOCKET, SO_KEEPALIVE, &v, sizeof(v));
}
```
5.1.16 shutdown()

**Description**
Stops specific activities on a socket.

**Prototype**

```c
int shutdown(int hSock, 
             int How);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| How       | One of the following modes:  
            • SHUT_RD: No more receive operations.  
            • SHUT_WR: No more send operations.  
            • SHUT_RDWR: No more receive & send operations. |

**Return value**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>-1</td>
<td>SOCKET_ERROR</td>
</tr>
</tbody>
</table>

**Additional information**

A `shutdown()` call causes all or a part of a full-duplex connection on the socket associated to be shut down. If `How` is SHUT_RD, then further receives will be disallowed. If `How` is SHUT_WR, then further sends will be disallowed. If `How` is 2, then further receives and sends will be disallowed. The shutdown function does not block regardless of the SO_LINGER setting on the socket.
5.1.17  socket()

Description
Creates a socket.

Prototype

```c
int socket(int Domain,
           int Type,
           int Proto);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Domain</td>
<td>Protocol family which should be used.</td>
</tr>
<tr>
<td>Type</td>
<td>Specifies the type of the socket.</td>
</tr>
<tr>
<td>Proto</td>
<td>Specifies the protocol which should be used with the socket. Must be set to zero except when Type is SOCK_RAW.</td>
</tr>
</tbody>
</table>

Return value

= -1   In case of error.
≥ 0    Socket handle.

Valid values for parameter Domain

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AF_INET</td>
<td>IPv4 - Internet protocol version 4</td>
</tr>
<tr>
<td>AF_INET6</td>
<td>IPv6 - Internet protocol version 6</td>
</tr>
</tbody>
</table>

Valid values for parameter Type

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOCK_STREAM</td>
<td>Stream socket</td>
</tr>
<tr>
<td>SOCK_DGRAM</td>
<td>Datagram socket</td>
</tr>
<tr>
<td>SOCK_RAW</td>
<td>RAW socket</td>
</tr>
</tbody>
</table>

Additional information

The Domain parameter specifies a communication domain within which communication will take place; the communication domain selects the protocol family which should be used. The protocol family generally is the same as the address family for the addresses supplied in later operations on the socket.

A SOCK_STREAM socket provides sequenced, reliable, two-way connection based byte streams. A SOCK_DGRAM socket supports datagrams (connectionless, unreliable messages of a fixed - typically small - maximum length).

Sockets of type SOCK_STREAM are full-duplex byte streams, similar to UNIX pipes. A stream socket must be in a connected state before it can send or receive data.

A connection to another socket is created with a connect() call. Once connected, data can be transferred using send() and recv() calls. When a session has been completed, a closesocket() should be performed.

The communications protocols used to implement a SOCK_STREAM ensure that data is not lost or duplicated. If a piece of data (for which the peer protocol has buffer space) cannot be successfully transmitted within a reasonable length of time, then the connection is considered broken and calls will return -1 which indicates an error. The protocols optionally keep sockets "warm" by forcing transmissions roughly every minute in the absence of oth-
er activity. An error is then indicated if no response can be elicited on an otherwise idle connection for a extended period (such as five minutes).

When receiving data from a socket of type `SOCK_STREAM` only up to the requested amount of data is consumed from the socket buffer upon calling a receive routine. Excess bytes of a message remain in the socket buffer and are available upon further calls to the receive routine.

When receiving data from a socket that is not of type `SOCK_STREAM` like a socket of type `SOCK_DGRAM` or `SOCK_RAW` one complete message (in the chunk as it was received) will be consumed and excess bytes of this message that are not read out of the buffer will be discarded and are not available for further calls to the receive routine.

`SOCK_DGRAM` sockets allow sending of datagrams to correspondents named in `sendto()` calls. Datagrams are generally received with `recvfrom()`, which returns the next datagram with its return address.

`SOCK_RAW` sockets allow receiving data including network and IP header and allow sending of data either with or without specifying the IP header yourself. RAW sockets are operated the same way as `SOCK_DGRAM` sockets but allow the ability to receive data including the IP and protocol header and to implement your own protocol. For using RAW sockets it is mandatory to call `IP_RAW_Add` on page 118 during the initialization of the stack. More information about RAW sockets can be found below.

The operation of sockets is controlled by socket-level options. The `getsockopt()` and `setsockopt()` functions are used to get and set options. Refer to `getsockopt` on page 269 and `setsockopt` on page 280 for detailed information.

**RAW sockets (receiving)**

For RAW sockets the `Proto` parameter specifies the IP protocol that will be received using this socket. Protocols registered to be used with `IP_*Add()` will be handled the stack and can not be used with RAW sockets at the same time. Using `IPPROTO_RAW` will receive data for any protocol not handled by the IP stack.

**RAW sockets (sending)**

For RAW sockets the `Proto` parameter specifies the IP protocol that will be entered into the IP header when sending data using this socket. Using `IPPROTO_RAW` for `Proto` for a sending socket results in the same as setting the socket option `IP_HDRINCL` for this socket by using `setsockopt` on page 280 and requires the user to include his own IP header in the data to send.
5.1.18  IP_RAW_AddPacketToSocket()

Description
Adds a packet and its data to a RAW socket (buffer). The current pData pointer and Num-Bytes of the packet will be used for the payload that will be added to the RAW socket (buffer).

Prototype

```c
int IP_RAW_AddPacketToSocket ( int          hSock,
                              IP_PACKET *  pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle of a RAW socket.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Packet to add to socket (buffer).</td>
</tr>
</tbody>
</table>

Return value

≥ 0  O.K., packet is now handled by the stack.
< 0  Error. Packet has to be freed by application.

Additional information

This function can be used to imitate a packet socket using RAW socket API. As the new data gets stored into the socket buffer without traversing all the way through other layers like IPv4, it is more effective but lacks a proper IP header. Therefore things like getting the source address using `recvfrom()` is not supported and will return invalid data.
5.1.19 IP_SOCKET_GetAddrFam()

Description
Returns the IP version of a socket (IPv4 or IPv6).

Prototype
U16 IP_SOCKET_GetAddrFam(int hSock);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle</td>
</tr>
</tbody>
</table>

Return value

0         Invalid socket handle
AF_INET   IPv4 socket.
AF_INET6  IPv6 socket.
5.1.20  IP_SOCKET_GetLocalPort()

Description

Returns the local port of a socket.

Prototype

U16 IP_SOCKET_GetLocalPort(int hSock);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle</td>
</tr>
</tbody>
</table>

Return value

> 0  OK. Local port number of the socket in network byte order.
= 0  Error. Socket not available or no local port bound to socket.
5.1.21   IP_SOCKET_CloseAll()

Description
Closes all socket handles that are open. Can be used to close all sockets in case of changing the local IP address or similar actions that change connection parameters.

Prototype

```c
void IP_SOCKET_CloseAll(U32 ConfMask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConfMask</td>
<td>Bitwise-OR bit mask of configurations:</td>
</tr>
<tr>
<td></td>
<td>• CLOSE_ALL_KEEP_LISTEN: Keep listening sockets.</td>
</tr>
</tbody>
</table>

Example: Closing all webserver child tasks

The following code closes all webserver child tasks for example if the target has changed its IP address. The parent listening socket shall be kept open as it is independent from the IP address and typically listens to any address of the system.

```c
OS_EnterRegion(); // Avoid being disturbed by disabling task switches.
// // End all child tasks that might access sockets.
for (i = 0; i < MAX_CONNECTIONS; i++) {
    r = OS_IsTask(&_aWebTasks[i]);
    if (r != 0) {
        OS_TerminateTask(&_aWebTasks[i]);
    }
}
// // Close all sockets that might been abandoned but // leave open listening parent sockets.
// IP_SOCKET_CloseAll(CLOSE_ALL_KEEP_LISTEN);
OS_LeaveRegion(); // Allow task switches again.
```
5.1.22 IP_SOCK_recvfrom_ts()

Description
Receives a datagram and stores the source address and timestamp.

Prototype

```c
int IP_SOCK_recvfrom_ts(int hSock, char * pData, int NumBytes, int Flags, sockaddr * pFrom, int * pAddrLen, IP_PACKET_TIMESTAMP * pTimestamp);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Handle on the socket.</td>
</tr>
<tr>
<td>pData</td>
<td>A pointer to a buffer for incoming data.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes of the buffer.</td>
</tr>
<tr>
<td>Flags</td>
<td>OR-combination of flags (MSG_PEEK).</td>
</tr>
<tr>
<td>pFrom</td>
<td>An optional pointer to a buffer where the address of the connecting entity is stored. The format of the address depends on the defined address family which was defined when the socket was created. Can be NULL.</td>
</tr>
<tr>
<td>pAddrLen</td>
<td>An optional pointer to an integer where the length of the received address is stored. Just like the format of the address, the length of the address depends on the defined address family.</td>
</tr>
<tr>
<td>pTimestamp</td>
<td>Pointer where to store the packet timestamp. Can be NULL.</td>
</tr>
</tbody>
</table>

Return value

= -1    Error occurred.
≥ 0     Number of bytes received.

Additional information

Requires IP_SUPPORT_PACKET_TIMESTAMP and/or IP_SUPPORT_PTP to be enabled.
5.1.23 IP_TCP_Accept()

Description
Registers a callback that will be executed upon a new client.

Prototype

```c
int IP_TCP_Accept
    ( IP_TCP_ACCEPT_HOOK * pHook,
        void                  (  * pfAccept )
    (int hSock , IP_TCP_ACCEPT_INFO * pInfo , void * pContext ),
    int hSock,
    void * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Management element of type IP_TCP_ACCEPT_HOOK.</td>
</tr>
<tr>
<td>pfAccept</td>
<td>Callback to register.</td>
</tr>
<tr>
<td>hSock</td>
<td>Parent socket handle (needs to have bind() and listen() done).</td>
</tr>
<tr>
<td>pContext</td>
<td>Custom context that will be passed to the callback.</td>
</tr>
</tbody>
</table>

Return value

= 0     O.K.
≠ 0     Error.

Additional information

The registered callback has to prevent any blocking situation. Calling send() for example on a non-blocking socket is fine.

Only clients fitting the registered parent socket will be reported to the callback like a regular accept() call. Therefore the usual steps like calling bind() and listen() are still necessary.
### 5.1.24 IP_FD_CLR()

**Description**

Removes a socket from a set.

**Prototype**

```c
void IP_FD_CLR(int hSock, IP_fd_set * pSet);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSet</td>
<td>Pointer on a set of type IP_fd_set.</td>
</tr>
</tbody>
</table>
5.1.25  IP_FD_SET()

Description
Adds a socket to a set.

Prototype

```c
void IP_FD_SET(int hSock,
               IP_fd_set * pSet);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSet</td>
<td>Pointer on a set of type IP_fd_set.</td>
</tr>
</tbody>
</table>
5.1.26 IP_FD_ISSET()

Description
Checks if a socket is part of a set.

Prototype
```
int IP_FD_ISSET(int hSock,
                IP_fd_set * pSet);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pSet</td>
<td>Pointer on a set of type IP_fd_set.</td>
</tr>
</tbody>
</table>

Return value

- 1  Socket is part of the set.
- 0  Socket is not part of the set.
5.2 Data structures

5.2.1 Structure sockaddr

Description
This structure holds socket address information for many types of sockets.

Prototype

```c
struct sockaddr {
    U16     sa_family;
    char     sa_data[14];
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sa_family</td>
<td>Address family. Normally AF_INET.</td>
</tr>
<tr>
<td>sa_data</td>
<td>The character array sa_data contains the destination address and port number for the socket.</td>
</tr>
</tbody>
</table>

Additional information

The structure sockaddr is mostly used as function parameter. To deal with struct sockaddr, a parallel structure struct sockaddr_in is implemented. The structure sockaddr_in is the same size as structure sockaddr, so that a pointer can freely be casted from one type to the other. Refer to Structure sockaddr_in on page 295 for more information and an example.
5.2.2 Structure sockaddr_in

Description
Structure for handling Internet addresses.

Prototype

```c
struct sockaddr_in {
    short sin_family;
    unsigned short sin_port;
    struct in_addr sin_addr;
    char sin_zero[8];
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin_family</td>
<td>Address family. Normally AF_INET.</td>
</tr>
<tr>
<td>sin_port</td>
<td>Port number for the socket.</td>
</tr>
<tr>
<td>sin_addr</td>
<td>Structure of type in_addr. The structure represents a 4-byte number that represents one digit in an IP address per byte.</td>
</tr>
<tr>
<td>sin_zero</td>
<td>sin_zero member is unused.</td>
</tr>
</tbody>
</table>

Example
Refer to `connect` on page 263 for an example.
5.2.3 Structure in_addr

Description
4-byte number that represents one digit in an IP address per byte.

Prototype

```c
struct in_addr {
    unsigned long s_addr;
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s_addr</td>
<td>Number that represents one digit in an IP address per byte.</td>
</tr>
</tbody>
</table>
5.2.4 Structure hostent

Description
The hostent structure is used by functions to store information about a given host, such as host name, IPv4 address, and so on.

Prototype

```c
struct hostent {
    char *    h_name;
    char **   h_aliases;
    int       h_addrtype;
    int       h_length;
    char **   h_addr_list;
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h_name</td>
<td>Official name of the host.</td>
</tr>
<tr>
<td>h_aliases</td>
<td>Alias list.</td>
</tr>
<tr>
<td>s_addrtype</td>
<td>Host address type.</td>
</tr>
<tr>
<td>h_length</td>
<td>Length of the address.</td>
</tr>
<tr>
<td>s_addr_list</td>
<td>List of addresses from the name server.</td>
</tr>
</tbody>
</table>
## 5.3 Error codes

The following table contains a list of generic error codes, generally full success is 0. Definite errors are negative numbers, and indeterminate conditions are positive numbers.

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Programming errors</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IP_ERR_PARAM</td>
<td>-10</td>
<td>Bad parameter.</td>
</tr>
<tr>
<td>IP_ERR_LOGIC</td>
<td>-11</td>
<td>Sequence of events that shouldn’t happen.</td>
</tr>
<tr>
<td><strong>System errors</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IP_ERR_NOMEM</td>
<td>-20</td>
<td>malloc() or calloc() failed.</td>
</tr>
<tr>
<td>IP_ERR_NOBUFFER</td>
<td>-21</td>
<td>Run out of free packets.</td>
</tr>
<tr>
<td>IP_ERR_RESOURCE</td>
<td>-22</td>
<td>Run out of other queue-able resource.</td>
</tr>
<tr>
<td>IP_ERR_BAD_STATE</td>
<td>-23</td>
<td>TCP layer error.</td>
</tr>
<tr>
<td>IP_ERR_TIMEOUT</td>
<td>-24</td>
<td>Timeout error on TCP layer.</td>
</tr>
<tr>
<td><strong>Networking errors</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IP_ERR_BAD_HEADER</td>
<td>-32</td>
<td>Bad header at upper layer (for upcalls).</td>
</tr>
<tr>
<td>IP_ERR_NO_ROUTE</td>
<td>-33</td>
<td>Can not find a reasonable next IP hop.</td>
</tr>
<tr>
<td><strong>Networking errors</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IP_ERR_SEND_PENDING</td>
<td>1</td>
<td>Packet queued pending an ARP reply.</td>
</tr>
<tr>
<td>IP_ERR_NOT_MINE</td>
<td>2</td>
<td>Packet was not of interest (upcall reply).</td>
</tr>
</tbody>
</table>
Chapter 6

TCP zero-copy interface

The TCP protocol can be used via socket functions or the TCP zero-copy interface which is described in this chapter.
6.1 TCP zero-copy

This section documents an optional extension to the Sockets layer, the TCP zero-copy API. The TCP zero-copy API is intended to assist the development of higher-performance embedded network applications by allowing the application direct access to the TCP/IP stack packet buffers. This feature can be used to avoid the overhead of having the stack copy data between application-owned buffers and stack-owned buffers in send() and recv(), but the application has to fit its data into, and accept its data from, the stack buffers.

The TCP zero-copy API is small because it is simply an extension to the existing Sockets API that provides an alternate mechanism for sending and receiving data on a socket. The Sockets API is used for all other operations on the socket.

6.1.1 Allocating, freeing and sending TCP packet buffers

The two functions for allocating and freeing packet buffers are straightforward requests:

IP_TCP_Alloc() allocates a packet buffer from the pool of packet buffers on the stack and IP_TCP_Free() frees a packet buffer. Applications using the TCP zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

The functions for sending data, IP_TCP_Send() and IP_TCP_SendAndFree(), send a packet buffer of data using a socket. The TCP zero-copy interface supports two different approaches to send and free a packet. One approach is that the stack frees the packet independent from the success of sending the packet. Therefore, IP_TCP_SendAndFree() is called to send and free the packet. It frees the packet independent from the success of the send operation. The other approach is that IP_TCP_Send() is called. In this case it is the responsibility of the application to free the packet. Depending on the return value the application can decide if IP_TCP_Free() should be called to free the packet.

6.1.2 Callback function for TCP zero-copy

Applications that use the TCP Zero-copy API for receiving data must include a callback function for acceptance of received packets, and must register the callback function with the socket using the setsockopt() sockets function with the SO_CALLBACK option name. The callback function, once registered, receives not only received data packets, but also connection events that result in socket errors.
6.2 Sending data with the TCP zero-copy API

To send data with the TCP zero-copy API, you should proceed as follow:
1. Allocating a packet buffer
2. Filling the allocated buffer
3. Sending the packet

The following section describes the procedure for allocating a packet buffer, sending data, and freeing the packet buffer step by step.

6.2.1 Allocating a packet buffer for TCP zero-copy

The first step in using the TCP zero-copy API to send data is to allocate a packet buffer from the stack using the `IP_TCP_Alloc()` function. This function takes the maximum length of the data you intend to send in the buffer as argument and returns a pointer to an `IP_PACKET` structure.

```c
IP_PACKET * pPacket;
U32 DataLen; // Amount of data to send

DataLen = 512; // Should indicate amount of data to send
pPacket = IP_TCP_Alloc(DataLen);
if (pPacket == NULL) {
    // Error, could not allocate packet buffer
}
```

This limits how much data you can send in one call using the TCP zero-copy API, as the data sent in one call to `IP_TCP_Send()` must fit in a single packet buffer. The actual limit is determined by the big packet buffer size, less 68 bytes for protocol headers. If you try to request a larger buffer than this, `IP_TCP_Alloc()` returns `NULL` to indicate that it cannot allocate a sufficiently large buffer.

6.2.2 Filling the allocated buffer with data for TCP zero-copy

Having allocated the packet buffer, you now fill it with the data to send. The function `IP_TCP_Alloc()` has initialized the returned `IP_PACKET` `pPacket` and so `pPacket->pData` points to where you can start depositing data.

6.2.3 Sending the TCP zero-copy packet

Finally, you send the packet by giving it back to the stack using the function `IP_TCP_Send()`.

```c
e = IP_TCP_Send(socket, pPacket);
if (e < 0) {
    IP_TCP_Free(pPacket);
}
```

This function sends the packet over TCP, or returns an error. If its return value is less than zero, it has not accepted the packet and the application has to decide either to free the packet or to retain it for sending later. Use `IP_TCP_SendAndFree()` if the packet should be freed automatically in any case.
6.3 Receiving data with the TCP zero-copy API

To receive data with the TCP zero-copy API, you should proceed as follow:
1. Writing a callback function
2. Registering the callback function

6.3.1 Writing a callback function for TCP zero-copy

Using the TCP zero-copy API for receiving data requires the application developer to write a callback function that the stack can use to inform the application of received data packets and other socket events. This function is expected to conform to the following prototype:

```c
int rx_callback(long Socket, IP_PACKET * pPacket, int code);
```

The stack calls this function when it has received a data packet or other event to report for a socket. The parameter `Socket` identifies the socket. The parameter `pPacket` passes a pointer to the packet buffer (if there is a packet buffer). If `pPacket` is not NULL, it is a pointer to a packet buffer containing received data for the socket. `pPacket->pData` points to the start of the received data, and `pPacket->NumBytes` indicates the number of bytes of received data in this buffer.

The parameter `code` passes an error event (if there is an error to report). If `code` is not 0, it is a socket error indicating that an error or other event has occurred on the socket. Typical nonzero values are `ESHUTDOWN` and `ECONNRESET`. `ESHUTDOWN` defines that the connected peer has closed its end of the connection and sends no more data. `ECONNRESET` defines that the connected peer has abruptly closed its end of the connection and neither sends nor receives more data.

Returned values

The callback function may return one of the following values:

<table>
<thead>
<tr>
<th>Symbolic</th>
<th>Numerical</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_OK</td>
<td>0</td>
<td>Data handled, packet can be freed.</td>
</tr>
<tr>
<td>IP_OK_KEEP_PACKET</td>
<td>1</td>
<td>Data will be handled by application later, the stack should NOT free the packet. This will be done by the application at a later time when the data has been handled and the packet is no longer needed.</td>
</tr>
</tbody>
</table>

Note: The callback function is called from the stack and is expected to return promptly. Some of the places where the stack calls the callback function require that the data structures on the stack remain consistent through the callback, so the callback function must not call back into the stack except to call `IP_TCP_Free()`.

6.3.2 Registering the TCP zero-copy callback function

The application must also inform the stack of the callback function. `setsockopt()` function provides an additional socket option, `SO_CALLBACK`, which should be used for this purpose once the socket has been created. The following code fragment illustrates the use of this option to register a callback function named `RxUpcall()` on the socket `Socket`:

```c
setsockopt(Socket, SOL_SOCKET, SO_CALLBACK, (void *)RxUpcall, 0);
```

See the function `setsockopt` on page 280 for more details.
## 6.4 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_TCP_Alloc()</td>
<td>Allocates a packet buffer large enough to hold Num-Bytes bytes of TCP data, plus TCP, IP and MAC headers.</td>
</tr>
<tr>
<td>IP_TCP_AllocEx()</td>
<td>Allocates a packet buffer large enough to hold Num-Bytes bytes of TCP data, plus TCP, IP and MAC headers.</td>
</tr>
<tr>
<td>IP_TCP_Free()</td>
<td>Free a packet allocated by IP_TCP_Alloc().</td>
</tr>
<tr>
<td>IP_TCP_Send()</td>
<td>Sends a packet buffer on a socket.</td>
</tr>
<tr>
<td>IP_TCP_SendAndFree()</td>
<td>Sends a packet buffer on a socket.</td>
</tr>
</tbody>
</table>
6.4.1 IP_TCP_Alloc()

Description
Allocates a packet buffer large enough to hold NumBytes bytes of TCP data, plus TCP, IP and MAC headers.

Prototype
IP_PACKET *IP_TCP_Alloc(int NumBytes);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytes</td>
<td>Length of the data which should be sent.</td>
</tr>
</tbody>
</table>

Return value
≠ NULL  Success, pointer to the allocated buffer.
= NULL   Error.

Additional information
This function must be called to allocate a buffer for sending data via IP_TCP_Send(). It returns the allocated packet buffer with its pPacket->pData field set to where the application must deposit the data to be sent.

This datasize limits how much data that you can send in one call using the TCP zero-copy API, as the data sent in one call to IP_TCP_Send() must fit in a single packet buffer, with the TCP, IP, and lower-layer headers that the stack needs to add in order to send the packet.

The actual limit is determined by the big packet buffer size (normally 1516 bytes). Refer to IP_AddBuffers() for more information about defining buffer sizes. If you try to request a larger buffer than this, IP_TCP_Alloc() returns NULL to indicate that it cannot allocate a sufficiently-large buffer.

Example

```c
IP_PACKET * pPacket;
U32 DataLen;       // Amount of data to send

DataLen = 1024;    // Should indicate amount of data to send
pPacket = IP_TCP_Alloc(DataLen);
if (pPacket == NULL) {
    // Error, could not allocate packet buffer
}
```
6.4.2 IP_TCP_AllocEx()

Description
Allocates a packet buffer large enough to hold `NumBytes` bytes of TCP data, plus TCP, IP and MAC headers.

Prototype

```
IP_PACKET *IP_TCP_AllocEx(int NumBytes,
                        int NumBytesHeader);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytes</td>
<td>Length of the data which should be sent.</td>
</tr>
<tr>
<td>NumBytesHeader</td>
<td>Size of all headers (Ethernet + IPvX + TCPvX).</td>
</tr>
</tbody>
</table>

Return value

≠ NULL Success, pointer to the allocated buffer.
= NULL Error.

Additional information

For further information please refer to `IP_TCP_Alloc()`.
6.4.3 IP_TCP_Free()

Description
Free a packet allocated by IP_TCP_Alloc().

Prototype

```c
void IP_TCP_Free ( IP_PACKET * p );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p</td>
<td>Pointer to the IP_Packet structure.</td>
</tr>
</tbody>
</table>
6.4.4 IP_TCP_Send()

Description
Sends a packet buffer on a socket.

Prototype

```c
int IP_TCP_Send(int hSock, 
                 IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Pointer to the IP_PACKET structure.</td>
</tr>
</tbody>
</table>

Return value

= 0  The packet was sent successfully.
< 0  The packet was not accepted by the stack. The application must re-send the packet using a call to IP_TCP_Send(), or free the packet using IP_TCP_Free().
> 0  The packet has been accepted and queued on the socket but has not yet been transmitted.

Additional information

Applications using the TCP zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

Packets have to be freed after processing. The TCP zero-copy interface supports two different approaches to free a packet. One approach is that the stack frees the packet independently from the success of sending the packet. Therefore, IP_TCP_SendAndFree() is called to send the packet and free the packet. It frees the packet independently from the success of the send operation. The other approach is that IP_TCP_Send() is called. In this case it is the responsibility application programmer to free the packet. Depending on the return value the application programmer can decide if IP_TCP_Free() should be called to free the packet.
6.4.5 IP_TCP_SendAndFree()

Description
Sends a packet buffer on a socket.

Prototype

```c
int IP_TCP_SendAndFree(int hSock,
                        IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket handle.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Pointer to the IP_PACKET structure.</td>
</tr>
</tbody>
</table>

Return value

- = 0     The packet was sent successfully.
- < 0     The packet was not accepted by the stack.
- > 0     The packet has been accepted and queued on the socket but has not yet been transmitted.

Additional information

Applications using the TCP zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

IP_TCP_SendAndFree() frees packet pPacket after processing. It frees the packet independent from the success of the send operation.
Chapter 7

UDP zero-copy interface

The UDP transfer protocol can be used via socket functions or the zero-copy interface which is described in this chapter.
7.1 UDP zero-copy

The UDP zero-copy API functions are provided for systems that do not need the overhead of sockets. These routines impose a lower demand on CPU and system memory requirements than sockets. However, they do not offer the portability of sockets.

UDP zero-copy API functions are intended to assist the development of higher-performance embedded network applications by allowing the application direct access to the UDP/IP stack packet buffers. This feature can be used to avoid the overhead of having the stack copy data between application-owned buffers and stack-owned buffers in `sendto()` and `recvfrom()`, but the application has to fit its data into, and accept its data from the stack buffers. Refer to `embOS/IP UDP discover (IP_UDPDiscover.c/IP_UDPDiscover_ZeroCopy.c)` on page 63 for detailed information about the UDP zero-copy example application.

7.1.1 Allocating, freeing and sending UDP packet buffers

The two functions for allocating and freeing packet buffers are straightforward requests: `IP_UDP_Alloc()` allocates a packet buffer from the pool of packet buffers on the stack and `IP_UDP_Free()` frees a packet buffer. Applications using the UDP zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

The functions for sending data, `IP_UDP_Send()` and `IP_UDP_SendAndFree()`, send a packet buffer of data using a port. The UDP zero-copy interface supports two different approaches to send and free a packet. One approach is that the stack frees the packet independent from the success of sending the packet. Therefore, `IP_UDP_SendAndFree()` is called to send and free the packet. It frees the packet independent from the success of the send operation. The other approach is that `IP_UDP_Send()` is called. In this case it is the responsibility of the application to free the packet. Depending on the return value the application can decide if `IP_UDP_Free()` should be called to free the packet.

7.1.2 Callback function for UDP zero-copy

Applications that use the UDP zero-copy API for receiving data must include a call-back function for acceptance of received packets, and must register the callback function with a port using the `IP_UDP_Open()` function. The callback function, once registered, receives all matching data packets.
7.2 Sending data with the UDP zero-copy API

To send data with the UDP zero-copy API, you should proceed as follow:

1. Allocating a packet buffer
2. Filling the allocated buffer
3. Sending the packet

The following section describes the procedure for allocating a packet buffer, sending data, and freeing the packet buffer step by step.

7.2.1 Allocating a packet buffer for UDP zero-copy

The first step in using the UDP zero-copy API to send data is to allocate a packet buffer from the stack using the `IP_UDP_Alloc()` function. This function takes the maximum length of the data you intend to send in the buffer as argument and returns a pointer to an `IP_PACKET` structure.

```c
IP_PACKET * pPacket;
U32 DataLen; // Amount of data to send

DataLen = 512; // Should indicate amount of data to send
pPacket = IP_UDP_Alloc(DataLen);
if (pPacket == NULL) {
   // Error, could not allocate packet buffer
}
```

This limits how much data you can send in one call using the UDP zero-copy API, as the data sent in one call to `IP_UDP_Send()` must fit in a single packet buffer. The actual limit is determined by the big packet buffer size, less typically 42 bytes for protocol headers (14 bytes for Ethernet header, 20 bytes IP header, 8 bytes UDP header). If you try to request a larger buffer than this, `IP_UDP_Alloc()` returns `NULL` to indicate that it cannot allocate a sufficiently large buffer.

7.2.2 Filling the allocated buffer with data for UDP zero-copy

Having allocated the packet buffer, you now fill it with the data to send. The function `IP_UDP_Alloc()` has initialized the returned `IP_PACKET pPacket` and so `pPacket->pData` points to where you can start depositing data.

7.2.3 Sending the UDP zero-copy packet

Finally, you send the packet by giving it back to the stack using the function `IP_UDP_Send()`.

```c
#define SRC_PORT 50020
#define DEST_PORT 50020
#define DEST_ADDR 0xC0A80101

e = IP_UDP_Send(0, htonl(DEST_ADDR), SRC_PORT, DEST_PORT, pPacket);
if (e < 0) {
   IP_UDP_Free(pPacket);
}
```

This function sends the packet over UDP, or returns an error. If its return value is less than zero, it has not accepted the packet and the application has to decide either to free the packet or to retain it for sending later. Use `IP_UDP_SendAndFree()` if the packet should be freed automatically in any case.
7.3 Receiving data with the UDP zero-copy API

To receive data with the UDP zero-copy API, you should proceed as follow:
1. Writing a callback function
2. Registering the callback function

7.3.1 Writing a callback function for UDP zero-copy

Using the UDP zero-copy API for receiving data requires the application developer to write a
callback function that the stack can use to inform the application of received data packets.
This function is expected to conform to the following prototype:

```c
int rx_callback(IP_PACKET * pPacket, void * pContext)
```

The stack calls this function when it has received a data packet for a port. The parameter
pPacket points to the packet buffer. The packet buffer contains the received data for the
socket. pPacket->pData points to the start of the received data, and pPacket->NumBytes
indicates the number of bytes of received data in this buffer.

Returned values

The callback function may return one of the following values:

<table>
<thead>
<tr>
<th>Symbolic</th>
<th>Numerical</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_OK</td>
<td>0</td>
<td>Data handled. embOS/IP will free the packet.</td>
</tr>
<tr>
<td>IP_OK_KEEP_PACKET</td>
<td>1</td>
<td>Data will be handled by application later, the stack should NOT free the packet. This will be done by the application at a later time when the data has been handled and the packet is no longer needed.</td>
</tr>
</tbody>
</table>

Note: The callback function is called from the stack and is expected to return promptly. Some of the places where the stack calls the callback function require that the data structures on the stack remain consistent through the callback, so the callback function must not call back into the stack except to call IP_UDP_Free().

7.3.2 Registering the UDP zero-copy callback function

The application must also inform the stack of the callback function. This is done by calling
the IP_UDP_Open() function. The following code fragment illustrates the use of this option
to register a callback function named RxUpcall() on the port 50020:

```c
#define SRC_PORT 50020
#define DEST_PORT 50020

IP_UDP_Open(0L /* any foreign host */, SRC_PORT, DEST_PORT, RxUpCall, 0L /* any tag */);
```

For further information, refer to IP_UDP_Open on page 325.
### 7.4 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_UDP_Alloc()</td>
<td>Returns a pointer to a packet buffer big enough for the specified sizes.</td>
</tr>
<tr>
<td>IP_UDP_Close()</td>
<td>Closes a UDP connection handle and removes the connection from demux table list of connections and deallocates it.</td>
</tr>
<tr>
<td>IP_UDP_FindFreePort()</td>
<td>Obtains a random port number that is suitable for use as the LPort parameter in a call to IP_UDP_Open().</td>
</tr>
<tr>
<td>IP_UDP_Free()</td>
<td>Frees the buffer which was used for a packet.</td>
</tr>
<tr>
<td>IP_UDP_GetDataSize()</td>
<td>Returns the size of the data contained in the received UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_GetDataPtr()</td>
<td>Returns a pointer to the data contained in the received UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_GetDestAddr()</td>
<td>Extracts destination IP address information from a UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_GetFPort()</td>
<td>Extracts foreign port information from a UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_GetIFIndex()</td>
<td>Extracts the zero-based interface index of the given UDP Packet.</td>
</tr>
<tr>
<td>IP_UDP_GetLPort()</td>
<td>Extracts local port information from a UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_GetSrcAddr()</td>
<td>Extracts source IP address information from a UDP packet.</td>
</tr>
<tr>
<td>IP_UDP_Open()</td>
<td>Creates a UDP connection to receive and pass upwards UDP packets that match the parameters passed.</td>
</tr>
<tr>
<td>IP_UDP_OpenEx()</td>
<td>Creates a UDP connection to receive, and pass upwards UDP packets that match the parameters passed.</td>
</tr>
<tr>
<td>IP_UDP_Send()</td>
<td>Sends an UDP packet to a specified host.</td>
</tr>
<tr>
<td>IP_UDP_SendAndFree()</td>
<td>Sends an UDP packet to a specified host and frees the packet.</td>
</tr>
<tr>
<td>IP_UDP_ReducePayloadLen()</td>
<td>Reduces the payload length of an allocated packet.</td>
</tr>
</tbody>
</table>
7.4.1 IP_UDP_Alloc()

Description
Returns a pointer to a packet buffer big enough for the specified sizes.

Prototype

IP_PACKET * IP_UDP_Alloc(int NumBytesData);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytesData</td>
<td>Length of the data which should be sent.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL    Success, pointer to the allocated buffer.
= NULL    Error.

Additional information

Applications using the UDP zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

The UDP zero-copy interface supports two different approaches to free a packet. One approach is that the stack frees the packet independent from the success of sending the packet. Therefore, IP_UDP_SendAndFree() is called to send the packet and free the packet. It frees the packet independent from the success of the send operation. The other approach is that IP_UDP_Send() is called. In this case it is the responsibility of the application to free the packet. Depending on the return value the application programmer can decide if IP_UDP_Free() should be called to free the packet.
7.4.2  IP_UDP_Close()

Description
Closes a UDP connection handle and removes the connection from demux table list of
connections and deallocates it.

Prototype

void IP_UDP_Close(IP_UDP_CONNECTION * pCon);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pCon</td>
<td>Pointer on the UDP connection.</td>
</tr>
</tbody>
</table>
7.4.3 IP_UDP_FindFreePort()

Description
Obtains a random port number that is suitable for use as the LPort parameter in a call to IP_UDP_Open().

Prototype
U16 IP_UDP_FindFreePort (void);

Return value
A usable port number in local endianess.

Additional information
The returned port number is suitable for use as the LPort parameter in a call to IP_UDP_Open(). Refer to IP_UDP_Open() for more information. IP_UDP_FindFreePort() avoids picking port numbers in the reserved range 0-1024, or in the range 1025-1199, which may be used for server applications.
7.4.4  IP_UDP_Free()

Description
Frees the buffer which was used for a packet.

Prototype

```
void IP_UDP_Free(IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>
7.4.5 IP_UDP_GetDataSize()

Description
Returns the size of the data contained in the received UDP packet.

Prototype
U16 IP_UDP_GetDataSize(const IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value
Size of the data contained in the received UDP packet.
7.4.6   IP_UDP_GetDataPtr()

Description
Returns a pointer to the data contained in the received UDP packet.

Prototype

void *IP_UDP_GetDataPtr(const IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value

Pointer to the data part of the UDP packet.
7.4.7 IP_UDP_GetDestAddr()

Description
Extracts destination IP address information from a UDP packet.

Prototype

```c
void IP_UDP_GetDestAddr ( const IP_PACKET * pPacket,
                         void       * pDestAddr,
                         int          AddrLen );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
<tr>
<td>pDestAddr</td>
<td>Pointer to a buffer to store the destination address.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>Size of the buffer used to store the destination address.</td>
</tr>
</tbody>
</table>
7.4.8   IP_UDP_GetFPort()

**Description**
Extracts foreign port information from a UDP packet.

**Prototype**
```
U16 IP_UDP_GetFPort(const IP_PACKET * pPacket);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

**Return value**
Foreign port of the packet.
7.4.9 IP_UDP_GetIFIndex()

Description
Extracts the zero-based interface index of the given UDP Packet.

Prototype

`unsigned IP_UDP_GetIFIndex(const IP_PACKET * pPacket);`

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pPacket</code></td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value
Zero-based interface index on which the packet was received.
7.4.10  IP_UDP_GetLPort()

Description
Extracts local port information from a UDP packet.

Prototype

U16 IP_UDP_GetLPort(const IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value
Local port of the packet.
7.4.11 IP_UDP_GetSrcAddr()

**Description**
Extraction source IP address information from a UDP packet.

**Prototype**
```c
void IP_UDP_GetSrcAddr ( const IP_PACKET * pPacket,
                        void       * pSrcAddr,
                        int          AddrLen );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
<tr>
<td>pSrcAddr</td>
<td>Pointer to a buffer to store the source address.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>Size of the buffer used to store the source address.</td>
</tr>
</tbody>
</table>
7.4.12  IP_UDP_Open()

Description
Creates a UDP connection to receive and pass upwards UDP packets that match the parameters passed.

Prototype

\[
\text{IP_UDP_CONNECTION } * \text{IP_UDP_Open (IP_ADDR FAddr,} \\
\text{U16 FPort,} \\
\text{U16 LPort,} \\
\text{int ( *handler)(IP_PACKET *, void *),} \\
\text{void * pContext);}\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAddr</td>
<td>Foreign IP address in network endianess.</td>
</tr>
<tr>
<td>FPort</td>
<td>Foreign port in host endianess.</td>
</tr>
<tr>
<td>LPort</td>
<td>Local port in host endianess.</td>
</tr>
<tr>
<td>handler</td>
<td>Callback function which is called when a UDP packet is received.</td>
</tr>
<tr>
<td>pContext</td>
<td>Application defined context pointer.</td>
</tr>
</tbody>
</table>

Return value

\[ \neq \text{NULL} \quad \text{Success, pointer to the UDP connection.} \]
\[ = \text{NULL} \quad \text{Error.} \]

Additional information

The parameters \text{FAddr, FPort}, \text{LPort}, can be set to 0 as a wild card, which enables the reception of broadcast datagrams. The callback \text{handler} function is called with a pointer to a received datagram and a copy of the data pointer which is passed to \text{IP_UDP_Open()}. This can be any data the programmer requires, such as a pointer to another function, or a control structure to help in demultiplexing the received UDP packet.

The returned handle is used as parameter for \text{IP_UDP_Close()} only. If \text{IP_UDP_Close()} is not called, there is no need to save the return value.
7.4.13  IP_UDP_OpenEx()

Description
Creates a UDP connection to receive, and pass upwards UDP packets that match the parameters passed.

Prototype

```c
IP_UDP_CONNECTION * IP_UDP_OpenEx ( IP_ADDR   FAddr ,
U16       FPort ,
IP_ADDR   LAddr ,
U16       LPort ,
int        (  * handler)( IP_PACKET *  ,  void  *  ),
void     *  pContext );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAddr</td>
<td>Foreign IP address in network endianess.</td>
</tr>
<tr>
<td>FPort</td>
<td>Foreign port in host endianess.</td>
</tr>
<tr>
<td>LAddr</td>
<td>Local IP address in network endianess.</td>
</tr>
<tr>
<td>LPort</td>
<td>Local port in host endianess.</td>
</tr>
<tr>
<td>handler</td>
<td>Callback function which is called when a UDP packet is received.</td>
</tr>
<tr>
<td>pContext</td>
<td>Application defined context pointer.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL   Success, pointer to the UDP connection.
= NULL   Error.

Additional information

The parameters FAddr, FPort, LAddr and LPort, can be set to 0 as a wild card, which enables the reception of broadcast datagrams. The callback handler function is called with a pointer to a received datagram and a copy of the data pointer which is passed to IP_UDP_OpenEx(). This can be any data the programmer requires, such as a pointer to another function, or a control structure to help in demultiplexing the received UDP packet.

The returned handle is used as parameter for IP_UDP_Close() only. If IP_UDP_Close() is not called, there is no need to save the return value.
7.4.14  IP_UDP_Send()

Description
Sends an UDP packet to a specified host. Contrarily to IP_RAW_SendAndFree(), it does not free the packet in case of error.

Prototype

```c
int IP_UDP_Send(int          IFace,
                 IP_ADDR     FHost,
                 U16         fport,
                 U16         lport,
                 IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>FHost</td>
<td>IP address of the target host in network endianess.</td>
</tr>
<tr>
<td>fport</td>
<td>Foreign port in host endianess.</td>
</tr>
<tr>
<td>lport</td>
<td>Local port in host endianess.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Data which should be sent to the target host.</td>
</tr>
</tbody>
</table>

Return value

- 0  Success.
- 1  IP_ERR_SEND_PENDING. Packet is waiting for address resolution (Incoming ARP response).
- < 0 Error code.

Additional information

The packet pPacket has to be allocated by calling IP_UDP_Alloc(). Refer to IP_UDP_Alloc() for detailed information.

If you expect to get any response to this packet you should have opened a UDP connection prior to calling IP_UDP_Send(). Refer to IP_UDP_Open() for more information about creating an UDP connection.

IP_UDP_Send() does not free the packet in case of an error. In this case it is the responsibility of the application to either free the packet using IP_UDP_Free() or to try sending the packet again.
7.4.15  IP_UDP_SendAndFree()

Description
Sends an UDP packet to a specified host and frees the packet.

Prototype

```
int IP_UDP_SendAndFree( int IFace,
                        IP_ADDR FHost,
                        U16 fport,
                        U16 lport,
                        IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>FHost</td>
<td>IP address of the target host in network endianess.</td>
</tr>
<tr>
<td>fport</td>
<td>Foreign port in host endianess.</td>
</tr>
<tr>
<td>lport</td>
<td>Local port in host endianess.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Data which should be sent to the target host.</td>
</tr>
</tbody>
</table>

Return value

- 0  Success.
- 1  Packet is queued for sending (IP_ERR_SEND_PENDING).
- < 0 Error code.

Additional information

The packet `pPacket` has to be allocated by calling `IP_UDP_Alloc()`. Refer to `IP_UDP_Alloc()` for detailed information.

If you expect to get any response to this packet you should have opened a UDP connection prior to calling this. Refer to `IP_UDP_Open()` for more information about creating an UDP connection.

Packets are always freed by calling `IP_UDP_SendAndFree()`. Therefore, no call of `IP_UDP_Free()` is required.
7.4.16 IP_UDP_ReducePayloadLen()

Description
Reduces the payload length of an allocated packet.

Prototype

```c
int IP_UDP_ReducePayloadLen ( IP_PACKET * pPacket, int NumBytes );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to previously allocated packet.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Reduced payload len.</td>
</tr>
</tbody>
</table>

Return value

< 0 Error, `NumBytes` parameter is bigger than current len. Other: O.K., current payload len.

Additional information
A previously allocated packet might have been allocated bigger than necessary to be on the safe side. This function allows to reduce the number of bytes that will be sent to the real amount necessary. The payload len can only be reduced. Trying to increase it (again) is returned as error.
Chapter 8

RAW zero-copy interface

Transferring RAW data can be used via socket functions or the zero-copy interface which is described in this chapter.
8.1 RAW zero-copy

The RAW zero-copy API functions are provided for systems that do not need the overhead of sockets. These routines impose a lower demand on CPU and system memory requirements than sockets. However, they do not offer the portability of sockets.

RAW zero-copy API functions are intended to assist the development of higher-performance embedded network applications by allowing the application direct access to the IP stack packet buffers. This feature can be used to avoid the overhead of having the stack copy data between application-owned buffers and stack-owned buffers in `sendto()` and `recvfrom()`, but the application has to fit its data into, and accept its data from the stack buffers.

To enable RAW socket support in the IP stack it is mandatory to call `IP_RAW_Add()` during initialization of the stack.

8.1.1 Allocating, freeing and sending packet buffers for RAW Zero-Copy

The two functions for allocating and freeing packet buffers are straightforward requests:

`IP_RAW_Alloc()` allocates a packet buffer from the pool of packet buffers on the stack and `IP_RAW_Free()` frees a packet buffer. Applications using the RAW zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

The functions for sending data, `IP_RAW_Send()` and `IP_RAW_SendAndFree()`, send a packet buffer of data using a specific protocol or sending pure data which requires the user to include his own IP header. The RAW zero-copy interface supports two different approaches to send and free a packet. One approach is that the stack frees the packet independent from the success of sending the packet. Therefore, `IP_RAW_SendAndFree()` is called to send and free the packet. It frees the packet independent from the success of the send operation. The other approach is that `IP_RAW_Send()` is called. In this case it is the responsibility of the application to free the packet. Depending on the return value the application can decide if `IP_RAW_Free()` should be called to free the packet.

8.1.2 Callback function for RAW Zero-Copy

Applications that use the RAW zero-copy API for receiving data must include a callback function for acceptance of received packets, and must register the callback function with a protocol using the `IP_RAW_Open()` function. The callback function, once registered, receives all matching data packets.
8.2 Sending data with the RAW zero-copy API

To send data with the RAW zero-copy API, you should proceed as follow:
1. Allocating a packet buffer
2. Filling the allocated buffer
3. Sending the packet

The following section describes the procedure for allocating a packet buffer, sending data, and freeing the packet buffer step by step.

8.2.1 Allocating a packet buffer for RAW Zero-Copy

The first step in using the RAW zero-copy API to send data is to allocate a packet buffer from the stack using the `IP_RAW_Alloc()` function. This function takes the maximum length of the data you intend to send in the buffer and if the IP header will be written by the stack or by yourself as arguments and returns a pointer to an `IP_PACKET` structure.

```c
IP_PACKET * pPacket;
U32 DataLen; // Amount of data to send

DataLen = 512; // Should indicate amount of data to send
pPacket = IP_RAW_Alloc(0, DataLen, 0); // Stack will write IP header
if (pPacket == NULL) {
    // Error, could not allocate packet buffer
}
```

This limits how much data you can send in one call using the RAW zero-copy API, as the data sent in one call to `IP_RAW_Send()` must fit in a single packet buffer. The actual limit is determined by the big packet buffer size, less typically 34 bytes for protocol headers (14 bytes for Ethernet header, 20 bytes IP header). If you try to request a larger buffer than this, `IP_RAW_Alloc()` returns NULL to indicate that it cannot allocate a sufficiently large buffer.

If you decide to provide the IP header yourself you can allocate a packet buffer the following way:

```c
pPacket = IP_RAW_Alloc(0, DataLen, 1);
```

In this case the packet size allocate limit is determined by the big packet buffer size, less typically 14 bytes for the Ethernet header.

8.2.2 Filling the allocated buffer with data for RAW Zero-Copy

Having allocated the packet buffer, you now fill it with the data to send. The function `IP_RAW_Alloc()` has initialized the returned `IP_PACKET` `pPacket` and so `pPacket->pData` points to where you can start depositing data.

Depending on if you decided to provide your own IP header you will have to store this data starting at `pPacket->pData` as well.

8.2.3 Sending the packet

Finally, you send the packet by giving it back to the stack using the function `IP_RAW_Send()`.

```c
#define PROTOCOL 1 // ICMP
#define DEST_ADDR 0xC0A80101

e = IP_RAW_Send(0, DEST_ADDR, PROTOCOL, pPacket);
if (e < 0) {
    IP_RAW_Free(pPacket);
}
```
This function sends the packet specifying the ICMP protocol in the IP header, or returns an error. If its return value is less than zero, it has not accepted the packet and the application has to decide either to free the packet or to retain it for sending later. Use IP_RAW_SendAndFree() if the packet should be freed automatically in any case.

In case you intend to provide your own IP header the protocol passed has to be IPPROTO_RAW. This prevents the stack to generate and include a header on its own.
8.3 Receiving data with the RAW zero-copy API

To receive data with the RAW zero-copy API, you should proceed as follow:
1. Writing a callback function
2. Registering the callback function

8.3.1 Writing a callback function

Using the RAW zero-copy API for receiving data requires the application developer to write a callback function that the stack can use to inform the application of received data packets. This function is expected to conform to the following prototype:

```c
int rx_callback(IP_PACKET * pPacket, void * pContext)
```

The stack calls this function when it has received a data packet for a protocol. The parameter `pPacket` points to the packet buffer. The packet buffer contains the received data for the socket. `pPacket->pData` points to the start of the received data (including network and IP header), and `pPacket->NumBytes` indicates the number of bytes of received data in this buffer.

Returned values

The callback function may return one of the following values:

<table>
<thead>
<tr>
<th>Symbolic</th>
<th>Numerical</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_OK</td>
<td>0</td>
<td>Data handled. embOS/IP will free the packet.</td>
</tr>
<tr>
<td>IP_OK_KEEP_PACKET</td>
<td>1</td>
<td>Data will be handled by application later, the stack should NOT free the packet. This will be done by the application at a later time when the data has been handled and the packet is no longer needed.</td>
</tr>
</tbody>
</table>

Notes: The callback function is called from the stack and is expected to return promptly. Some of the places where the stack calls the callback function require that the data structures on the stack remain consistent through the callback, so the callback function must not call back into the stack except to call `IP_RAW_Free()`.

8.3.2 Registering the callback function for RAW Zero-Copy

The application must also inform the stack of the callback function. This is done by calling the `IP_RAW_Open()` function. The following code fragment illustrates the use of this option to register a callback function named `RxUpCall()` for the ICMP protocol:

```c
#define PROTOCOL 1    // ICMP
IP_RAW_Open(0L /* any foreign host */, 0L /* any local host */, PROTOCOL, RxUpCall, 0L /* any tag */);
```

See function `IP_RAW_Open` on page 345 for reference.

To receive ICMP packets the ICMP protocol has not to be added to the stack by calling `IP_ICMP_Add()`. Protocols known to the stack and added for handling through the stack can not be used with the RAW zero-copy API.
### 8.4 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_RAW_Alloc()</td>
<td>Returns a pointer to a packet buffer big enough for the specified sizes.</td>
</tr>
<tr>
<td>IP_RAW_Close()</td>
<td>Closes a RAW connection handle and removes the connection from demux table list of connections and deallocates it.</td>
</tr>
<tr>
<td>IP_RAW_Free()</td>
<td>Frees the buffer which was used for a packet.</td>
</tr>
<tr>
<td>IP_RAW_GetDataPtr()</td>
<td>Returns pointer to data contained in the received RAW packet.</td>
</tr>
<tr>
<td>IP_RAW_GetDataSize()</td>
<td>Returns size of the payload in the received RAW packet.</td>
</tr>
<tr>
<td>IP_RAW_GetDestAddr()</td>
<td>Extracts destination IP address information from a RAW packet.</td>
</tr>
<tr>
<td>IP_RAW_GetIFIndex()</td>
<td>Retrieves the zero-based interface index of the given RAW Packet.</td>
</tr>
<tr>
<td>IP_RAW_GetSrcAddr()</td>
<td>Extracts source address information from a RAW packet.</td>
</tr>
<tr>
<td>IP_RAW_Open()</td>
<td>Creates a RAW connection handle to receive, and pass upwards RAW packets that match the parameters passed.</td>
</tr>
<tr>
<td>IP_RAW_Send()</td>
<td>Send a RAW packet to a specified host.</td>
</tr>
<tr>
<td>IP_RAW_SendAndFree()</td>
<td>Sends a RAW Packet to a specified host and frees the packet.</td>
</tr>
<tr>
<td>IP_RAWReducePayloadLen()</td>
<td>Reduces the payload length of an allocated packet.</td>
</tr>
</tbody>
</table>
8.4.1  IP_RAW_Alloc()

Description
Returns a pointer to a packet buffer big enough for the specified sizes.

Prototype

IP_PACKET * IP_RAW_Alloc(unsigned IFaceId,
                        unsigned NumBytesData,
                        int       IpHdrIncl);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based index of available interfaces.</td>
</tr>
<tr>
<td>NumBytesData</td>
<td>Length of the data which should be sent.</td>
</tr>
<tr>
<td>IpHdrIncl</td>
<td>Specifies if the IP header is generated or has to be provided by the user. 0: Header generated by the stack; 1: Header to be provided in the packet data by the user.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL   Success, pointer to the allocated buffer.
= NULL   Error.

Additional information

Applications using the RAW zero-copy API are responsible for allocating packet buffers for use in sending data, as well as for freeing buffers that have been used to receive data and those that the application has allocated but decided not to use for sending data. As these packet buffers are a limited resource, it is important that applications free them promptly when they are no longer of use.

The RAW zero-copy interface supports two different approaches to free a packet. One approach is that the stack frees the packet independent from the success of sending the packet. Therefore, IP_RAW_SendAndFree() is called to send the packet and free the packet. It frees the packet independent from the success of the send operation. The other approach is that IP_RAW_Send() is called. In this case it is the responsibility of the application to free the packet. Depending on the return value the application programmer can decide if IP_RAW_Free() should be called to free the packet.
8.4.2 IP_RAW_Close()

Description
Closes a RAW connection handle and removes the connection from demux table list of connections and deallocates it.

Prototype

```c
void IP_RAW_Close(IP_RAW_CONNECTION * pCon);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pCon</td>
<td>RAW Connection handle.</td>
</tr>
</tbody>
</table>
8.4.3  IP_RAW_Free()

Description
Frees the buffer which was used for a packet.

Prototype

void IP_RAW_Free(IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>
8.4.4 IP_RAW.GetDataPtr()

Description
Returns pointer to data contained in the received RAW packet

Prototype

```c
void *IP_RAW.GetDataPtr(const IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value
Pointer to the data part of the packet.

Additional information
The data pointer returned points to the start of the network header. Therefore typically 34 bytes header (14 bytes Ethernet header, 20 bytes IP header) are included.
8.4.5  IP_RAW_GetDataSize()

Description
Returns size of the payload in the received RAW packet.

Prototype

U16 IP_RAW_GetDataSize(const IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value

Number of data bytes received in the packet.
8.4.6 IP_RAW_GetDestAddr()

Description
Extracts destination IP address information from a RAW packet.

Prototype

```c
void IP_RAW_GetDestAddr(const IP_PACKET * pPacket,
                          void       * pDestAddr,
                          int          AddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
<tr>
<td>pDestAddr</td>
<td>Pointer to a buffer to store the destination address.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>Size of the buffer used to store the destination address.</td>
</tr>
</tbody>
</table>
8.4.7   IP_RAW_GetIFIndex()

Description
Retrieves the zero-based interface index of the given RAW Packet.

Prototype

unsigned IP_RAW_GetIFIndex(const IP_PACKET * pPacket);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
</tbody>
</table>

Return value
Zero-based interface index on which the packet was received.
8.4.8 IP_RAW_GetSrcAddr()

Description
Extracts source address information from a RAW packet.

Prototype

```c
void IP_RAW_GetSrcAddr(const IP_PACKET * pPacket,
                    void       * pSrcAddr,
                    int          AddrLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to a packet structure.</td>
</tr>
<tr>
<td>pSrcAddr</td>
<td>Pointer to a buffer to store the source address.</td>
</tr>
<tr>
<td>AddrLen</td>
<td>Size of the buffer used to store the source address.</td>
</tr>
</tbody>
</table>
8.4.9 IP_RAW_Open()

Description
Creates a RAW connection handle to receive, and pass upwards RAW packets that match the parameters passed.

Prototype

```c
IP_RAW_CONNECTION *IP_RAW_Open
    (IP_ADDR   FAddr,
     IP_ADDR   LAddr,
     U8        Protocol,
     int        ( *handler )( IP_PACKET * pPacket , void * pContext ),
     void     *  pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAddr</td>
<td>Foreign IP address.</td>
</tr>
<tr>
<td>LAddr</td>
<td>Local IP address.</td>
</tr>
<tr>
<td>Protocol</td>
<td>IP protocol.</td>
</tr>
<tr>
<td>handler</td>
<td>Callback function which is called when a packet of protocol “Protocol” is received.</td>
</tr>
<tr>
<td>pContext</td>
<td>Application defined context pointer.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL Success, pointer to the RAW connection handle.
= NULL Error.

Additional information

The parameters FAddr and LAddr can be set to 0 as a wild card, which enables the reception of broadcast packets. To enable the reception of any protocol use IPPROTO_RAW as Protocol. The callback handler function is called with a pointer to a received protocol and a copy of the data pointer which is passed to IP_RAW_Open(). This can be any data the application requires, such as a pointer to another function, or a control structure to aid in demultiplexing the received packet.

The returned handle is used as parameter for IP_RAW_Close() only. If IP_RAW_Close() is not called, there is no need to save the return value.
8.4.10 IP_RAW_Send()

Description
Send a RAW packet to a specified host. Contrarily to IP_RAW_SendAndFree(), it does not free the packet in case of error.

Prototype

```c
int IP_RAW_Send(int IFace, IP_ADDR FHost, U8 Protocol, IP_PACKET * pPacket);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based index of available interfaces.</td>
</tr>
<tr>
<td>FHost</td>
<td>IP address of the target host in network endianess.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Protocol that will be used in the IP header generated by the stack.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Packet that should be sent to the target host.</td>
</tr>
</tbody>
</table>

Return value

- = 0  O.K. Packet sent or in a sent fifo, to be on the wire shortly.
- = 1  IP_ERR_SEND_PENDING. Packet is waiting for address resolution (Incoming ARP response).
- < 0  Error code.

Additional information

The packet pPacket has to be allocated by calling IP_RAW_Alloc(). Refer to IP_RAW_Alloc() for detailed information.

If you expect to get any response to this packet you should have opened a RAW connection prior to calling IP_RAW_Send(). Refer to IP_RAW_Open() more information about creating a RAW connection.

IP_RAW_Send() does not free the packet after sending. It is the responsibility of the application to free the packet. Depending on the return value the application programmer can decide if IP_RAW_Free() should be called to free the packet.
8.4.11  IP_RAW_SendAndFree()

**Description**
Sends a RAW Packet to a specified host and frees the packet. Typically called from applications using zero-copy RAW communication. A packet sent with this function is normally allocated by calling `IP_RAW_Alloc()`.

**Prototype**

```c
int IP_RAW_SendAndFree(int IFace, IP_ADDR FHost, U8 Protocol, IP_PACKET * pPacket);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based index of available interfaces.</td>
</tr>
<tr>
<td>FHost</td>
<td>IP address of the target host in network endianess.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Protocol that will be used in the IP header generated by the stack.</td>
</tr>
<tr>
<td>pPacket</td>
<td>Packet that should be sent to the target host.</td>
</tr>
</tbody>
</table>

**Return value**

- = 0   O.K. Packet sent or in a sent fifo, to be on the wire shortly.
- = 1   IP_ERR_SEND_PENDING. Packet is waiting for address resolution (Incoming ARP response).
- < 0   Error code.

**Additional information**

The packet `pPacket` has to be allocated by calling `IP_RAW_Alloc()`. Refer to `IP_RAW_Alloc()` for detailed information.

If you expect to get any response to this packet you should have opened a RAW connection prior to calling `IP_RAW_Send()`. Refer to `IP_RAW_Open()` more information about creating a RAW connection.

Packets are always freed by calling `IP_RAW_SendAndFree()`. Therefore, no call of `IP_RAW_Free()` is required.
8.4.12 IP_RAW_ReducePayloadLen()

Description
Reduces the payload length of an allocated packet.

Prototype

```c
int IP_RAW_ReducePayloadLen ( IP_PACKET * pPacket,
                               int NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to previously allocated packet.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Reduced payload len.</td>
</tr>
</tbody>
</table>

Return value

< 0   Error, NumBytes parameter is bigger than current len. Other: O.K., current payload len.

Additional information

A previously allocated packet might have been allocated bigger than necessary to be on the safe side. This function allows to reduce the number of bytes that will be sent to the real amount necessary. The payload len can only be reduced. Trying to increase it (again) is returned as error.
Chapter 9

DHCP client

This chapter explains the usage of the Dynamic Host Control Protocol (DHCP) with embOS/IP. All API functions are described in this chapter.
9.1 DHCP backgrounds

DHCP stands for Dynamic Host Configuration Protocol. It is designed to ease configuration management of large networks by allowing the network administrator to collect all the IP hosts “soft” configuration information into a single computer. This includes IP address, name, gateway, and default servers. Refer to [RFC 2131] - DHCP - Dynamic Host Configuration Protocol for detailed information about all settings which can be assigned with DHCP.

DHCP is a “client/server” protocol, meaning that machine with the DHCP database “serves” requests from DHCP clients. The clients typically initiate the transaction by requesting an IP address and perhaps other information from the server. The server looks up the client in its database, usually by the client’s media address, and assigns the requested fields. Clients do not always need to be in the server’s database. If an unknown client submits a request, the server may optionally assign the client a free IP address from a “pool” of free addresses kept for this purpose. The server may also assign the client default information of the local network, such as the default gateway, the DNS server, and routing information.

When the IP addresses is assigned, it is “leased” to the client for a finite amount of time. The DHCP client needs to keep track of this lease time, and obtain a lease extension from the server before the lease time runs out. Once the lease has elapsed, the client should not send any more IP packets (except DHCP requests) until he get another address. This approach allows computers (such as laptops or factory floor monitors) which will not be permanently attached to the network to share IP addresses and not hog them when they are not using the net.

DHCP is just a superset of the Bootstrap Protocol (BOOTP). The main differences between the two are the lease concept, which was created for DHCP, and the ability to assign addresses from a pool. Refer to [RFC 951] - Bootstrap Protocol for detailed information about the Bootstrap Protocol.

Most of the IP_DHCPC_* API also applies to the BOOTP protocol. Therefore no separate API for BOOTP is available except for IP_BOOTPC_Activate().
## 9.2 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_BOOTPC_Activate()</td>
<td>Activates the <strong>BOOTP</strong> client for the specified interface.</td>
</tr>
<tr>
<td>IP_DHCPC_Activate()</td>
<td>Activates the <strong>DHCP</strong> client for the specified interface.</td>
</tr>
<tr>
<td>IP_DHCPC_AddStateChangeHook()</td>
<td>This function adds a hook function to the <code>IP_DHCPC_HOOK_ON_STATE_CHANGE</code> list.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigAlwaysStartInit()</td>
<td>Configures if the client always starts with INIT phase, sending a DISCOVER packet, even if an IP was configured for the interface before.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigDNSManually()</td>
<td>Configures if the client will request and use a received DNS server configuration.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigOnActivate()</td>
<td>Configures behavior regarding currently set parameters of an interface when the DHCP client is activated on this interface.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigOnFail()</td>
<td>Configures behavior regarding currently set parameters of an interface when the DHCP client fails in communication to negotiate a configuration with a server.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigOnLinkDown()</td>
<td>Configures behavior regarding currently set parameters of an interface when the DHCP client is activated on this interface and the link goes down.</td>
</tr>
<tr>
<td>IP_DHCPC_ConfigUniBcStartMode()</td>
<td>Configures if the client will start with unicast or broadcast messages first and enables automatic mode switching.</td>
</tr>
<tr>
<td>IP_DHCPC_GetState()</td>
<td>Returns the state of the DHCP client.</td>
</tr>
<tr>
<td>IP_DHCPC_Halt()</td>
<td>Stops DHCP client activity for the given network interface.</td>
</tr>
<tr>
<td>IP_DHCPC_Renew()</td>
<td>Sends a request with the currently in use DHCP configuration to the DHCP server to check if the configuration is still valid.</td>
</tr>
<tr>
<td>IP_DHCPC_SetCallback()</td>
<td>This function allows the caller to set a callback for an interface.</td>
</tr>
<tr>
<td>IP_DHCPC_SetClientId()</td>
<td>Sets the DHCP client id for the specified interface.</td>
</tr>
<tr>
<td>IP_DHCPC_SetTimeout()</td>
<td>Sets timeout parameters for DHCP requests.</td>
</tr>
</tbody>
</table>
9.2.1 IP_BOOTPC_Activate()

Description
Activates the BOOTP client for the specified interface.

Prototype

```c
void IP_BOOTPC_Activate(int IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Interface index.</td>
</tr>
</tbody>
</table>
9.2.2 IP_DHCPC_Activate()

Description
Activates the DHCP client for the specified interface.

Prototype

```c
void IP_DHCPC_Activate(int IFaceId, const char * sHost, const char * sDomain, const char * sVendor);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero based interface index.</td>
</tr>
<tr>
<td>sHost</td>
<td>Pointer to host name to use in negotiation. May be NULL.</td>
</tr>
<tr>
<td>sDomain</td>
<td>Pointer to domain name to use in negotiation. May be NULL.</td>
</tr>
<tr>
<td>sVendor</td>
<td>Pointer to vendor to use in negotiation. May be NULL.</td>
</tr>
</tbody>
</table>

Additional information

This function is typically called from within IP_X_Config(). This function initializes the DHCP client. It attempts to open a UDP connection to listen for incoming replies and begins the process of configuring a network interface using DHCP. The process may take several seconds, and the DHCP client will keep retrying if the service does not respond.

The parameters `sHost`, `sDomain`, `sVendor` are optional (can be NULL). If not NULL, must point to a memory area which remains valid after the call since the string is not copied.

Example

```c
// Correct function call
IP_DHCPC_Activate(0, "Target", NULL, NULL);

// Illegal function call
char ac;
sprintf(ac, "Target%d, Index);
IP_DHCPC_Activate(0, ac, NULL, NULL);

// Correct function call
static char ac;
sprintf(ac, "Target%d, Index);
IP_DHCPC_Activate(0, ac, NULL, NULL);
```

If you start the DHCP client with activated logging the output on the terminal I/O should be similar to the listing below:

```
DHCP: Sending discover!
DHCP: Received packet from 192.168.1.1
DHCP: Packet type is OFFER.
DHCP: Renewal time: 2160 min.
DHCP: Rebinding time: 3780 min.
DHCP: Lease time: 4320 min.
DHCP: Host name received.
DHCP: Sending Request.
DHCP: Received packet from 192.168.1.1
DHCP: Packet type is ACK.
DHCP: Renewal time: 2160 min.
DHCP: Rebinding time: 3780 min.
DHCP: Lease time: 4320 min.
DHCP: Host name received.
```
9.2.3 IP_DHCPC_AddStateChangeHook()

Description

This function adds a hook function to the IP_DHCPC_HOOK_ON_STATE_CHANGE list. Registered hooks will be called with every status change and reports some DHCP informations about the current status.

Prototype

```c
void IP_DHCPC_AddStateChangeHook(IP_DHCPC_HOOK_ON_STATE_CHANGE * pHook,
                                 void                             (  * pf )
                                   ( unsigned IFaceId , unsigned State , IP_DHCPC_STATE_INFO * pInfo ));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Element of type IP_DHCPC_HOOK_ON_STATE_CHANGE to register.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback that is notified on a state change. IFaceId: Zero-based interface index. State : Current DHCP client state. pInfo : Further information about the current state.</td>
</tr>
</tbody>
</table>

Additional information

This mechanism is provided so that the caller can do some processing when the interface is up (like doing initializations or blinking LEDs, etc.).

The pointer on IP_DHCPC_STATE_INFO structure will not be valid after the callback is called. If parameters are to be used, they need to be copied.
9.2.4 IP_DHCPC_ConfigAlwaysStartInit()

Description

Configures if the client always starts with INIT phase, sending a DISCOVER packet, even if an IP was configured for the interface before.

Prototype

```c
void IP_DHCPC_ConfigAlwaysStartInit(int IFaceId,
                                       U8 OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>OnOff</td>
<td>• 0: Off.</td>
</tr>
<tr>
<td></td>
<td>• 1: On.</td>
</tr>
</tbody>
</table>
9.2.5  IP_DHCPC_ConfigDNSManually()

Description
Configures if the client will request and use a received DNS server configuration.

Prototype
void IP_DHCPC_ConfigDNSManually(int IFaceId, 
    U8 OnOff);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0: Off, DNS configuration from server is used.  
                     • 1: On, DNS configuration needs to be set manually.  |
9.2.6 IP_DHCPC_ConfigOnActivate()

Description
Configures behavior regarding currently set parameters of an interface when the DHCP client is activated on this interface.

Prototype

```c
void IP_DHCPC_ConfigOnActivate(int IFaceId, U8 Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Mode</td>
<td>Mode to configure.</td>
</tr>
</tbody>
</table>

Additional information

This function needs to be called before activating the DHCP client for an interface using IP_DHCPC_Activate(). Please be aware that activating the DHCP client with a static configured IP address instructs the DHCP client to try to request this address from the server. In case IP_DHCPC_ConfigOnFail() is configured to use DHCP_RESET_CONFIG (default) it might happen that the static IP will be reset if no server is reachable or the IP addr. is declined from a server.

Possible values for Mode

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP_RESET_CONFIG</td>
<td>Reset interface when activating the DHCP client on this interface to avoid using old settings longer than necessary. Default.</td>
</tr>
<tr>
<td>DHCP_USE_STATIC_CONFIG</td>
<td>Keep previous static configuration, if any, as fallback configuration as long as no new configuration has been received from a server.</td>
</tr>
</tbody>
</table>
9.2.7  IP_DHCPC_ConfigOnFail()

Description
Configures behavior regarding currently set parameters of an interface when the DHCP client fails in communication to negotiate a configuration with a server.

Prototype

```c
void IP_DHCPC_ConfigOnFail(int IFaceId, U8 Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Mode</td>
<td>Mode to configure.</td>
</tr>
</tbody>
</table>

Additional information
This function shall be called before activating the DHCP client for an interface using IP_DHCPC_Activate()

Possible values for Mode

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCP_ARP_RESET_CONFIG</td>
<td>Reset interface to avoid using old settings longer than necessary as they might interfere with other DHCP clients in this network. Default.</td>
</tr>
<tr>
<td>DHCP_USE_STATIC_CONFIG</td>
<td>Setup previous static configuration, if any, as fallback configuration to remain accessible.</td>
</tr>
<tr>
<td>DHCP_USE_DHCP_CONFIG</td>
<td>Keep previously received DHCP configuration. Not recommended as it might interfere with other DHCP clients in this network.</td>
</tr>
</tbody>
</table>
9.2.8  IP_DHCPC_ConfigOnLinkDown()

Description
Configures behavior regarding currently set parameters of an interface when the DHCP client is activated on this interface and the link goes down.

Prototype

```c
void IP_DHCPC_ConfigOnLinkDown ( int IFaceId,
                                  U32 Timeout,
                                  U8  Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout to wait before reacting on link down [ms].</td>
</tr>
<tr>
<td>Mode</td>
<td>Mode to configure.</td>
</tr>
</tbody>
</table>

Additional information
This function shall be called before activating the DHCP client for an interface using IP_DHCPC_Activate().

Possible values for Mode

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCPC_RESET_CONFIG</td>
<td>Reset interface when link goes down on this interface to avoid using old settings longer than necessary as the target might be connected to another network. Default.</td>
</tr>
<tr>
<td>DHCPC_USE_STATIC_CONFIG</td>
<td>Setup previous static configuration, if any, as fallback configuration on link down to allow a quick start once the link goes up again.</td>
</tr>
<tr>
<td>DHCPC_USE_DHCP_CONFIG</td>
<td>Keep previously received DHCP configuration on link down as long as the configuration is not declined or a new configuration is received once link on this interface is up again.</td>
</tr>
</tbody>
</table>
9.2.9  IP_DHCPC_ConfigUniBcStartMode()

Description
Configures if the client will start with unicast or broadcast messages first and enables automatic mode switching.

Prototype

```c
void IP_DHCPC_ConfigUniBcStartMode(int IFaceId, U8 Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| Mode      | • 0: Start with uncasts first.  
           | • 1: Start with broadcasts first. |

Additional information

The mode switch will be applied after a couple of retries have been sent for the same message. The number of retries can be configured using **IP_DHCPC_SetTimeout()**.
9.2.10  IP_DHCPC_GetState()

Description
Returns the state of the DHCP client.

Prototype
unsigned IP_DHCPC_GetState(int IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

= 0  DHCP client not in use.
> 0  DHCP client in use.
9.2.11    IP_DHCPC_Halt()

Description
Stops DHCP client activity for the given network interface.

Prototype

void IP_DHCPC_Halt(int IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
9.2.12  IP_DHCPC_Renew()

Description
Sends a request with the currently in use DHCP configuration to the DHCP server to check if the configuration is still valid.

Prototype

```c
void IP_DHCPC_Renew(int IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
9.2.13  IP_DHCPC_SetCallback()

**Description**
This function allows the caller to set a callback for an interface.

**Prototype**

```c
void IP_DHCPC_SetCallback(int IFaceId,
                          int (*routine)(int IFaceId, int State ));
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>routine</td>
<td>Callback functions which should be called with every status changes.</td>
</tr>
</tbody>
</table>

**Additional information**

The callback is called with every status change. This mechanism is provided so that the caller can do some processing when the interface is up (like doing initializations or blinking LEDs, etc.).
9.2.14  IP_DHCPC_SetClientId()

Description
Sets the DHCP client id for the specified interface. Should be called prior to IP_DHCPC_Activate().

Prototype

```c
void IP_DHCPC_SetClientId(int IFaceId, const U8 *pClientId, unsigned ClientIdLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero based interface index.</td>
</tr>
<tr>
<td>pClientId</td>
<td>Pointer to ClientId to use in negotiation. Will not be copied.</td>
</tr>
<tr>
<td>ClientIdLen</td>
<td>Length of client ID.</td>
</tr>
</tbody>
</table>

Additional information

Typically a DHCP server will recognize a client based on its MAC address. A client ID can be included by the client when communicating with the server for identification if needed. Please be aware that one byte is prepend that contains the type of the ID. The client ID will not be copied into the stack, therefore you need to make sure that the memory will be available even after the call.

Bad example

```c
U8 ClientID[7]; // 1 byte type + 6 bytes MAC address.
ClientID[0] = 0x01; // Type = Ethernet.
IP_GetHWAddr(0, &ClientID[1], sizeof(ClientID) - 1);
IP_DHCPC_SetClientId(0, ClientID, sizeof(ClientID));
```

Good example

```c
static U8 ClientID[7]; // 1 byte type + 6 bytes MAC address.
ClientID[0] = 0x01; // Type = Ethernet.
IP_GetHWAddr(0, &ClientID[1], sizeof(ClientID) - 1);
IP_DHCPC_SetClientId(0, ClientID, sizeof(ClientID));
```
9.2.15 IP_DHCPC_SetTimeout()

Description
Sets timeout parameters for DHCP requests. RFC2131 demands exponential retransmission times (doubling retransmission time with each retry), but in practice it may make more sense to work with a fixed, non-exponential timeout.

Prototype

```c
void IP_DHCPC_SetTimeout ( int IFaceId ,
                         U32 Timeout,
                         U32 MaxTries,
                         unsigned Exponential);
```  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Interface index.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Value of the timeout.</td>
</tr>
<tr>
<td>MaxTries</td>
<td>Maximum number or attempts.</td>
</tr>
<tr>
<td>Exponential</td>
<td>Value used to delay new attempts.</td>
</tr>
</tbody>
</table>
Chapter 10

DHCP server (Add-on)

The embOS/IP implementation of the DHCP server is an optional extension to embOS/IP. It allows setting up a Dynamic Host Control Protocol (DHCP) server that seamlessly integrates with embOS/IP. All API functions are described in this chapter.
10.1 DHCP Backgrounds

DHCP stands for Dynamic Host Configuration Protocol. It is designed to ease configuration management of large networks by allowing the network administrator to collect all the IP hosts "soft" configuration information into a single computer. This includes IP address, name, gateway, and default servers. Refer to [RFC 2131] - DHCP - Dynamic Host Configuration Protocol for detailed information about all settings which can be assigned with DHCP.

Further information can be found in the chapter DHCP backgrounds on page 350 in the description of the DHCP client.
## 10.2 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_DHCPS_ConfigDNSAddr()</td>
<td>Configures one or more DNS addr.</td>
</tr>
<tr>
<td>IP_DHCPS_ConfigGWAddr()</td>
<td>Configures the default gateway to be assign to clients.</td>
</tr>
<tr>
<td>IP_DHCPS_ConfigMaxLeaseTime()</td>
<td>Configures the maximum lease time that a client will be granted to use the achieved configuration.</td>
</tr>
<tr>
<td>IP_DHCPS_ConfigPool()</td>
<td>Configures the IP address pool that can be assigned to DHCP clients.</td>
</tr>
<tr>
<td>IP_DHCPS_Halt()</td>
<td>Stops DHCP server activity for the passed interface.</td>
</tr>
<tr>
<td>IP_DHCPS_Init()</td>
<td>Initializes the DHCP server for the specified interface.</td>
</tr>
<tr>
<td>IP_DHCPS_SetReservedAddresses()</td>
<td>Sets a configuration for IP addresses to reserve for specific MAC addresses.</td>
</tr>
<tr>
<td>IP_DHCPS_Start()</td>
<td>Starts the DHCP server for the specified interface.</td>
</tr>
</tbody>
</table>
10.2.1  IP_DHCPS_ConfigDNSAddr()

Description
Configures one or more DNS addr. to assign to clients.

Prototype

```c
int IP_DHCPS_ConfigDNSAddr(unsigned IFIndex, U32 * paDNSAddr, U8 NumServers);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index of the server to configure.</td>
</tr>
<tr>
<td>paDNSAddr</td>
<td>Array of U32 IPv4 addresses of DNS servers to use (host order).</td>
</tr>
<tr>
<td>NumServers</td>
<td>Number of DNS servers in array.</td>
</tr>
</tbody>
</table>

Return value

0         O.K.
IP_ERR_MISC Error, server already started.
IP_ERR_PARAM Error, wrong interface.

Additional information

Configuring DNS server settings is optional. If no DNS servers are configured no DNS servers will be assigned to clients.

Needs to be called before activating the DHCP server for this interface with IP_DHCPS_Start().

Example

```c
U32 aDNSAddr[2];

// // Setup DNS addr. as needed.
//
aDNSAddr[0]  = IP_BYTES2ADDR(192, 168, 12, 1);
aDNSAddr[1]  = IP_BYTES2ADDR(192, 168, 12, 2);
IP_DHCPS_ConfigDNSAddr(0, &aDNSAddr[0], 2);
IP_DHCPS_ConfigPool(0, IP_BYTES2ADDR(192, 168, 12, 11), 0xFFFF0000, 20);
IP_DHCPS_Init(0);
IP_DHCPS_Start(0);
```
10.2.2 IP_DHCPS_ConfigGWAddr()

Description
Configures the default gateway to be assign to clients.

Prototype

```
int IP_DHCPS_ConfigGWAddr(unsigned IFIndex,
                        U32      GWAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index of the server to configure.</td>
</tr>
<tr>
<td>GWAddr</td>
<td>Default gateway IP address in host order.</td>
</tr>
</tbody>
</table>

Return value

- 0: O.K.
- IP_ERR_MISC: Error, server already started.
- IP_ERR_PARAM: Error, wrong interface.

Additional information

Configuring a gateway setting is optional. If no gateway is configured no gateway will be assigned to clients.

Needs to be called before activating the DHCP server for this interface with IP_DHCPS_Start().

Example

```
IP_DHCPS_ConfigGWAddr(0, IP_BYTES2ADDR(192, 168, 12, 1));
IP_DHCPS_ConfigPool(0, IP_BYTES2ADDR(192, 168, 12, 11), 0xFFFF0000, 20);
IP_DHCPS_Init(0);
IP_DHCPS_Start(0);
```
### 10.2.3 IP_DHCPS_ConfigMaxLeaseTime()

**Description**

Configures the maximum lease time that a client will be granted to use the achieved configuration.

**Prototype**

```c
int IP_DHCPS_ConfigMaxLeaseTime(unsigned IFIndex, U32 Seconds);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Seconds</td>
<td>Maximum lease time in seconds. Default 7200s =&gt; 2h. Up to 4294967 seconds, converted into ms this is the maximum we can store in an U32. 0xFFFFFFFF to grant infinite if asked for.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- IP_ERR_MISC: Error, server already started.
- IP_ERR_PARAM: Error, wrong interface or value for lease time invalid.

**Additional information**

Optional. Needs to be called before activating the DHCP server for this interface with IP_DHCPS_Start().

**Example**

```c
IP_DHCPS_ConfigMaxLeaseTime(0, 7200);
IP_DHCPS_ConfigPool(0, IP_BYTES2ADDR(192, 168, 12, 11), 0xFFFF0000, 20);
IP_DHCPS_Init(0);
IP_DHCPS_Start(0);
```
10.2.4 IP_DHCPS_ConfigPool()

Description
Configures the IP address pool that can be assigned to DHCP clients.

Prototype

```c
int IP_DHCPS_ConfigPool(unsigned IFIndex,
                        U32      StartIPAddr,
                        U32      SNMask,
                        U32      PoolSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index of the server to configure.</td>
</tr>
<tr>
<td>StartIPAddr</td>
<td>First IP address of the pool in host order.</td>
</tr>
<tr>
<td>SNMask</td>
<td>Subnet mask in host order.</td>
</tr>
<tr>
<td>PoolSize</td>
<td>Number of addresses in the pool starting from StartIPAddr. The pool size has to be at least 1.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>O.K.</td>
</tr>
<tr>
<td>IP_ERR_MISC</td>
<td>Error, server already started.</td>
</tr>
<tr>
<td>IP_ERR_PARAM</td>
<td>Error, wrong interface.</td>
</tr>
</tbody>
</table>

Additional information

Optional. Needs to be called before activating the DHCP server for this interface with IP_DHCPS_Start().

Example

```c
IP_DHCPS_ConfigPool(0, IP_BYTES2ADDR(192, 168, 12, 11), 0xFFFF0000, 20);
IP_DHCPS_Init(0);
IP_DHCPS_Start(0);
```
10.2.5 IP_DHCPS_Halt()

Description
Stops DHCP server activity for the passed interface.

Prototype

```c
void IP_DHCPS_Halt(unsigned IFIndex);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
10.2.6  **IP_DHCPS_Init()**

**Description**

Initializes the DHCP server for the specified interface.

**Prototype**

```
int IP_DHCPS_Init(unsigned IFIndex);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Return value**

- **0**  O.K.
- **IP_ERR_MISC**  Error, server already initialized.
- **IP_ERR_NO_MEM**  Error, not enough memory.
- **IP_ERR_PARAM**  Error, wrong interface.

**Additional information**

This function is obsolete. Its functionality has been implemented into **IP_DHCPS_ConfigPool()** as this needs to be called anyhow. This function is a dummy for the moment, so it does not hurt to call it like before.
10.2.7  IP_DHCPS_SetReservedAddresses()

Description
Sets a configuration for IP addresses to reserve for specific MAC addresses.

Prototype

```c
int IP_DHCPS_SetReservedAddresses(unsigned IFIndex, const IP_DHCPS_RESERVE_ADDR *paAddr, unsigned NumAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>paAddr</td>
<td>Pointer to array of IP_DHCPS_RESERVE_ADDR addresses.</td>
</tr>
<tr>
<td>NumAddr</td>
<td>Number of addresses at <code>paAddr</code>.</td>
</tr>
</tbody>
</table>

Return value

- `< 0`  Error
- `= 0`  O.K.

Additional information

For the moment the global configuration for subnet mask, gateway and DNS for the server on this interface is used.

IP addresses to be reserved are not limited to addresses of the configured pool. Of course addresses need to be within the configured subnet to work as expected.

Example

```c
const IP_DHCPS_RESERVE_ADDR _aReserved[] = {
    { (U8*) "\x00\x0C\x29\x76\xE7\x0B", IP_BYTES2ADDR(192,168,12,20) },
    { (U8*) "\xB8\x27\xEB\xC7\x96\x5F", IP_BYTES2ADDR(192,168,20,55) },
};

static void _StartServer(void) {
    IP_DHCPS_ConfigPool(0, IP_BYTES2ADDR(192, 168, 12, 11), IP_BYTES2ADDR(255, 255, 0, 0), 20);
    IP_DHCPS_Init(0);
    IP_DHCPS_SetReservedAddresses(0, _aReserved, SEGGER_COUNTOF(_aReserved));
    IP_DHCPS_Start(0);
}
```
### 10.2.8  IP_DHCPS_Start()

**Description**
Starts the DHCP server for the specified interface.

**Prototype**
```
int IP_DHCPS_Start(unsigned IFIndex);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFIndex</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- IP_ERR_MISC: Error, server already started or not initialized/configured.
- IP_ERR_NO_MEM: Error, not enough memory.
- IP_ERR_PARAM: Error, wrong interface.

**Additional information**

IP_DHCPS_Init() and IP_DHCPS_ConfigPool() needs to be called before activating the DHCP server for an interface in order to set at least the minimum configurations.
10.3 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the DHCP server modules presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

10.3.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP DHCP server</td>
<td>approximately 2.0 kByte</td>
</tr>
</tbody>
</table>

10.3.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP DHCP server</td>
<td>approximately 2.0 kByte</td>
</tr>
</tbody>
</table>

10.3.3 RAM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP DHCP server</td>
<td>approximately 200 bytes</td>
</tr>
</tbody>
</table>
Chapter 11

mDNS Server (Add-on)

The embOS/IP implementation of mDNS server which stands for multicast DNS server is an optional extension to embOS/IP. It makes your target easily discoverable and advertising services available throughout your network.

For the target IP address identification, this add-on also replies to Microsoft LLMNR requests.
11.1 embOS/IP mDNS

The embOS/IP mDNS implementation is an optional extension which can be seamlessly integrated into your TCP/IP application. It allows your target to be easily identified with a small memory footprint.

The mDNS server module implements the relevant parts of the following RFCs.

<table>
<thead>
<tr>
<th>Document</th>
<th>Download</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Contains an example application that run’s a simple mDNS server example.</td>
</tr>
<tr>
<td>IP</td>
<td>Contains the mDNS server file, IP_DISCOVER.c.</td>
</tr>
</tbody>
</table>
11.2 Feature list

- Low memory footprint.
- Makes your target easily discoverable.
- Easy to implement.
11.3 Requirements

TCP/IP stack

The embOS/IP mDNS server implementation requires the embOS/IP TCP/IP stack.
11.4 Multicast DNS background

Multicast DNS allows to find devices in an environment without the support of an actual DNS server. A DNS request is sent to a specific multicast address on a specific port. Servers are listening on this multicast address and handling the requests.

Multicast DNS handles only local systems and doen’t replace a real DNS for request outside the local network.

11.4.1 Hostname resolution

In order to get the IP address of a target by its name, two records could be sent:

- A: To get the IPv4 address.
- AAAA: To get the IPv6 address.

Apple and Microsoft are both proposing a similar solution but using different multicast IP addresses and ports. The Add-on is handling both specifications for A and AAAA requests.

The hostname is set in the configuration structure:

```c
static const IP_DNS_SERVER_CONFIG _Config = {
    .sHostname  =  "mytarget.local" ,
    .TTL        =  120 ,
    .NumConfig  =  3 ,
    .apSDConfig =  _SDConfig ,
};
```
11.4.2 Service discovery (mDNS-SD)

The add-on also provides the definition of some services through additional records:

- **PTR**: Pointer record.
- **SRV**: Service record.
- **TXT**: Text record.

The service discovery is only available through the Apple multicast address (use of Bonjour), or equivalent on Linux machines (like avahi).

For example, if a target runs a web server, a possible configuration is:

```c
static const IP_DNS_SERVER_SD_CONFIG _SDConfig[] = {
    {
        .Type                       = IP_DNS_SERVER_TYPE_PTR,  
        .Flags                      = IP_DNS_SERVER_FLAG_FLUSH,  
        .TTL                        = 0,  
        .Config = {
            .PTR   = {
                .sName          = "_http._tcp.local",  
                .sDomainName    = "myserver._http._tcp.local"  
            }  
        }  
    },  
    {
        .Type                       = IP_DNS_SERVER_TYPE_SRV,  
        .Flags                      = IP_DNS_SERVER_FLAG_FLUSH,  
        .TTL                        = 0,  
        .Config = {
            .SRV   = {
                .sName         = "myserver._http._tcp.local",  
                .Priority      = 0,  
                .Weight        = 0,  
                .Port          = 80,  
                .sTarget       = "mytarget.local"  
            }  
        }  
    },  
    {
        .Type                       = IP_DNS_SERVER_TYPE_TXT,  
        .Flags                      = IP_DNS_SERVER_FLAG_FLUSH,  
        .TTL                        = 0,  
        .Config = {
            .TXT   = {
                .sName         = "myserver._http._tcp.local",  
                .sTXT          = "PATH=/"  
            }  
        }  
    }  
};
```

1. **PTR record**
   - The PTR record indicates that an HTTP server runs at “myserver._http._tcp.local”

2. **SRV record**
   - The SRV record gives indication on the port number (80) and the actual local target name (mytarget)

3. **TXT record**
   - The TXT record gives additional information, for example the path to the web server.
   - It is possible to add A and AAAA records, but they are not needed if the target name corresponds to the target host name.
## 11.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MDNS_SERVER_Start()</td>
<td>Starts the LLNR/mDNS DNS-SD discovery service.</td>
</tr>
<tr>
<td>IP_MDNS_SERVER_Stop()</td>
<td>Stops the LLNR/mDNS DNS-SD discovery service.</td>
</tr>
</tbody>
</table>
11.5.1  IP_MDNS_SERVER_Start()

Description
Starts the LLMNR/mDNS DNS-SD discovery service.

Prototype

```c
int IP_MDNS_SERVER_Start(const IP_DNS_SERVER_CONFIG * pConfig);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pConfig</td>
<td>Pointer on the configuration array.</td>
</tr>
</tbody>
</table>

Return value

- 0       O.K.
- < 0     Error

Example

Configuration should define local names.

```c
static const IP_DNS_SERVER_CONFIG _Config = {
    .sHostname  = "mytarget.local",
    .TTL        = 120,
    .NumConfig  = 0, // No DNS-SD configuration.
    .apSDConfig = NULL
};
IP_MDNS_SERVER_Start(& _Config);
```
11.5.2  IP_MDNS_SERVER_Stop()

Description
Stops the LLMNR/mDNS DNS-SD discovery service.

Prototype

```c
int IP_MDNS.SERVER_Stop(void);
```

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK.</td>
</tr>
</tbody>
</table>
11.6 Data structures

11.6.1 Structure IP_DNS_SERVER_CONFIG

Description
This is the main configuration of the mDNS server.

Prototype

```c
typedef struct {
    const char* sHostname;
    U32 TTL;
    unsigned NumConfig;
    const IP_DNS_SERVER_SD_CONFIG* apSDConfig;
} IP_DNS_SERVER_CONFIG;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sHostname</td>
<td>Pointer on a null terminated string corresponding to the host name (for example “mytarget.local”)</td>
</tr>
<tr>
<td>TTL</td>
<td>Time to live in seconds. If set to 0 a default value defined in DNS_TTL_INIT is used.</td>
</tr>
<tr>
<td>NumConfig</td>
<td>Number of mDNS-SD configuration pointed by apSDConfig. Could be 0.</td>
</tr>
<tr>
<td>apSDConfig</td>
<td>Array of mDNS-SD configuration. Could be NULL if NumConfig is 0.</td>
</tr>
</tbody>
</table>
11.6.2 Structure IP_DNS_SERVER_SD_CONFIG

Description
Configuration of a mDNS-SD entry.

Prototype

```c
typedef struct {
    U32                        TTL;
    union  {
        IP_DNS_SERVER_A          A;
        #if  IP_SUPPORT_IPV6
            IP_DNS_SERVER_AAAA       AAAA;
        #endif
        IP_DNS_SERVER_PTR        PTR;
        IP_DNS_SERVER_SRV        SRV;
        IP_DNS_SERVER_TXT        TXT;
    }  Config;
    U8                         Type;
    U8                         Flags;
}  IP_DNS_SERVER_SD_CONFIG;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TTL</td>
<td>Time to live in seconds for this entry. If set to 0 the main TTL value from the structure IP_DNS_SERVER_CONFIG is used.</td>
</tr>
<tr>
<td>A</td>
<td>A record description. Not needed for the hostname. See IP_DNS_SERVER_A.</td>
</tr>
<tr>
<td>AAAA</td>
<td>AAA record description. Not needed for the hostname. See IP_DNS_SERVER_AAAA.</td>
</tr>
<tr>
<td>PTR</td>
<td>Pointer record description. See IP_DNS_SERVER_PTR.</td>
</tr>
<tr>
<td>SRV</td>
<td>Service record description. See IP_DNS_SERVER_SRV.</td>
</tr>
<tr>
<td>TXT</td>
<td>Text record description. See IP_DNS_SERVER_TXT.</td>
</tr>
<tr>
<td>Type</td>
<td>This is the type of the entry:</td>
</tr>
<tr>
<td></td>
<td>- IP_DNS_SERVER_TYPE_A</td>
</tr>
<tr>
<td></td>
<td>- IP_DNS_SERVER_TYPE_PTR</td>
</tr>
<tr>
<td></td>
<td>- IP_DNS_SERVER_TYPE_TXT</td>
</tr>
<tr>
<td></td>
<td>- IP_DNS_SERVER_TYPE_SRV</td>
</tr>
<tr>
<td></td>
<td>- IP_DNS_SERVER_TYPE_AAAA</td>
</tr>
<tr>
<td>Flags</td>
<td>Optional configuration flags for this entry.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_DNS_SERVER_FLAG_FLUSH</td>
<td>Sets the FLUSH bit when sending a response that contains this entry.</td>
</tr>
<tr>
<td></td>
<td>The FLUSH bit should be set on all unique resources like the primary host name or in general A and AAAA records. Unique entries in responses are meant to FLUSH all previously returned configurations. We do not set this flag automatically for ANY entry (not even A and AAAA) to allow maximum freedom in your configuration.</td>
</tr>
</tbody>
</table>
11.6.3 Structure IP_DNS_SERVER_A

Description
Description of an A record entry (IPv4 IP address). This is not needed to have an entry for the host name. An ‘A’ request with the host name gets automatically a reply with the current IP address of the interface on which the request is received.

If the field IPAddr is set to 0, the IP address of the host will be used automatically.

Prototype

```c
typedef struct {
    char* sName;
    IP_ADDR IPAddr;
} IP_DNS_SERVER_A;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Null terminated string of the server name.</td>
</tr>
<tr>
<td>IPAddr</td>
<td>IPv4 address of the server name.</td>
</tr>
</tbody>
</table>
11.6.4 Structure IP_DNS_SERVER_AAAA

Description

Description of a AAAA record entry (IPv6 IP address). This is not needed to have an entry for the host name. An 'AAAA' request with the host name gets automatically a reply with the current IP address of the interface on which the request is received.

If the field `aIPAddrV6` is completely set to 0 (the 16 bytes are all 0), the IP address of the host will be used automatically.

Prototype

```
typedef struct {
    char*                     sName;
    U8                       aIPAddrV6[IPV6_ADDR_LEN];
} IP_DNS_SERVER_AAAA;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Null terminated string of the server name.</td>
</tr>
<tr>
<td>aIPAddrV6</td>
<td>IPv6 address of the server name.</td>
</tr>
</tbody>
</table>
11.6.5 Structure IP_DNS_SERVER_PTR

Description
Description of a PTR record entry. This could either convert an IP address into a server name, for example 1.0.168.192.in-addr.arpa into myserver.local. Or this could be used to indicate the server that provides a service (like _http._tcp.local).

Prototype

```c
typedef struct {
    char*         sName;
    char*         sDomainName;
} IP_DNS_SERVER_PTR;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Null terminating string defining the entry that is requested. (what appears in the request).</td>
</tr>
<tr>
<td>sDomainName</td>
<td>Null terminating string. This is the reply. If set to NULL, the sHostname of the main config IP_DNS_SERVER_CONFIG is used.</td>
</tr>
</tbody>
</table>
### 11.6.6 Structure IP_DNS_SERVER_SRV

**Description**

Description of a SRV record entry. This describes which server provides a service and additional information like priority, port, ...

**Prototype**

```c
typedef struct {
    char * sName;
    U16    Priority;
    U16    Weight;
    U16    Port;
    char * sTarget;  // If NULL, hostname will be used.
} IP_DNS_SERVER_SRV;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>sName</strong></td>
<td>Null terminating string defining the entry that is requested, Service, Protocol and Name are concatenated. (what appears in the request).</td>
</tr>
<tr>
<td><strong>Priority</strong></td>
<td>Priority value: 0 is the higher priority.</td>
</tr>
<tr>
<td><strong>Weight</strong></td>
<td>Weight to balance between equivalent servers with the same priority.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Port providing the service.</td>
</tr>
<tr>
<td><strong>sTarget</strong></td>
<td>Null terminating string. This is the server name. If set to NULL, the sHostname of the main config IP_DNS_SERVER_CONFIG is used.</td>
</tr>
</tbody>
</table>
11.6.7 Structure IP_DNS_SERVER_TXT

Description
Description of a TXT record entry. This describes some textual parameters. There could be many TXT records for the same name defining many parameters, but in this case, they should be placed next to one another in the configuration structure.

Prototype

```c
typedef struct {
    char* sName;
    char* sTXT;
} IP_DNS_SERVER_TXT;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Null terminating string defining the entry that is requested. (what appears in the request).</td>
</tr>
<tr>
<td>sTXT</td>
<td>Null terminating string defining one text entry. For example “Version=1”</td>
</tr>
</tbody>
</table>
11.7 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the CoAP client/server presented in the tables below have been measured on a Cortex-M4 system with the default configuration.

11.7.1 ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP mDNS server</td>
<td>approximately 3.1 kBytes</td>
</tr>
</tbody>
</table>

11.7.2 RAM usage

The add-on uses a small internal table for the multicast UDP management.

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP mDNS server</td>

</tbody>
</table>
Chapter 12

DNS Server (Add-on)

This add-on provides a simple DNS server which allows for a server to handle the DNS requests it receives. This could be used to give the IP address of the target as a reply to a server enquiry. It is ideally coupled with the DHCP server (Add-on) on page 367.
12.1 embOS/IP DNS server

The embOS/IP DNS implementation is an optional extension which can be seamlessly integrated into your TCP/IP application.

The DNS server module implements the relevant parts of the following RFCs.

<table>
<thead>
<tr>
<th>Document</th>
<th>Download</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP</td>
<td>Contains the mDNS server file, IP_DISCOVER.c.</td>
</tr>
</tbody>
</table>
12.2 Feature list

- Low memory footprint.
- Makes your target easily discoverable.
- Easy to implement.
12.3 Requirements

TCP/IP stack

The embOS/IP DNS server implementation requires the embOS/IP TCP/IP stack.
12.4 Implementation

The embOS/IP simple DNS server used the same mechanism and configuration as the mDNS Server (Add-on) on page 379. Thus the structures and parameters won’t be described further in this chapter.

The only difference is that target name definition are not local anymore since a DNS is faked. Thus the “.local” extension is not needed anymore.
### 12.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_DNS_SERVER_Start()</td>
<td>Starts the simple DNS service.</td>
</tr>
<tr>
<td>IP_DNS_SERVER_Stop</td>
<td>Starts the simple DNS service.</td>
</tr>
</tbody>
</table>
### 12.5.1 IP_DNS_SERVER_Start()

**Description**

Starts the simple DNS service.

**Prototype**

```c
int IP_DNS_SERVER_Start(const IP_DNS_SERVER_CONFIG * pConfig);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pConfig</td>
<td>Pointer on the fake DNS configuration.</td>
</tr>
</tbody>
</table>

**Return value**

0 OK.

**Example**

Configuration should define local names.

```c
static const IP_DNS_SERVER_CONFIG _Config = {
    .sHostname  = "mytarget.eth",
    .TTL        = 120,
    .NumConfig  = 0,  // No DNS-SD configuration.
    .apSDConfig = NULL
};
IP_DNS_SERVER_Start(&_Config);
```
12.5.2 IP_DNS_SERVER_Stop
12.6 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the CoAP client/server presented in the tables below have been measured on a Cortex-M4 system with the default configuration.

In addition to the existing mDNS server add-on, the DNS server add-on adds approximately 0.2 kBytes of ROM.
Chapter 13

AutoIP

All functions which are required to add AutoIP to your application are described in this chapter.
13.1 embOS/IP AutoIP backgrounds

The embOS/IP AutoIP module adds the dynamic configuration of IPv4 Link-Local addresses to embOS/IP. This functionality is better known as AutoIP. Therefore, this term will be used in this document. The AutoIP implementation covers the relevant parts of the following RFCs:

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

In general AutoIP is a method to negotiate a IPv4 address in a network without the utilization of a server such as a DHCP server. AutoIP will try to use IPv4 addresses out of a reserved pool from the addresses 169.254.1.0 to 169.254.254.255 to find a free IP that is not used by any other network participant at this time.

To achieve this goal AutoIP sends ARP probes into the network to ask if the addr. to be used is already in use. This is determined by an ARP reply for the requested address. Upon an address conflict AutoIP will generate a new address to use and will retry to use it by sending ARP probes again.
## 13.2 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_AutoIP_Activate()</td>
<td>Activates AutoIP negotiation for the specified interface.</td>
</tr>
<tr>
<td>IP_AutoIP_Halt()</td>
<td>Stops AutoIP activity for the passed interface.</td>
</tr>
<tr>
<td>IP_AutoIP_SetUserCallback()</td>
<td>This function allows the caller to set a callback for an interface.</td>
</tr>
<tr>
<td>IP_AutoIP_SetStartIP()</td>
<td>Sets the IP address which will be used for the first configuration try.</td>
</tr>
</tbody>
</table>
13.2.1 IP_AutoIP_Activate()

Description
Activates AutoIP negotiation for the specified interface.

Prototype

```c
void IP_AutoIP_Activate(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero based interface index.</td>
</tr>
</tbody>
</table>

Additional information

Activating the dynamic configuration of IPv4 Link-Local addresses means that an additional timer will be added to the stack. This timer will be called every second to check the status of the address configuration. With the AutoIP activation an IP address for the dynamic configuration will be created. The IPv4 prefix 169.254/16 is registered with the IANA for this purpose. This means that embOS/IP will generate an IP address similar to 169.254.xxx.xxx. The subnet mask of is always 255.255.0.0.

In embOS/IP debug builds terminal I/O output can be enabled. AutoIP outputs status information in the terminal I/O window if the stack is configured to so (IP_MTYPE_AUTOIP added to the log filter mask). Please refer to IP_SetLogFilter on page 1173 and IP_AddLogFilter on page 1171 for further information about the enabling terminal I/O. If terminal I/O is enabled the output of the program start should be similar to the following lines:

```
0:000 MainTask - INIT: Init started. Version 2.00.06
0:000 MainTask - DRIVER: Found PHY with Id 0x2000 at addr 0x1
0:000 MainTask - INIT: Link is down
0:000 MainTask - INIT: Init completed
0:000 IP_Task - INIT: IP_Task started
0:000 IP_RxTask - INIT: IP_RxTask started
3:000 IP_Task - LINK: Link state changed: Full duplex, 100 MHz
9:000 IP_Task - AutoIP: 169.254.240.240 checked, no conflicts
```
13.2.2   IP_AutoIP_Halt()

Description
Stops AutoIP activity for the passed interface.

Prototype

```c
int IP_AutoIP_Halt(unsigned IFaceId,
                     char      KeepIP);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>KeepIP</td>
<td>Flag to indicate if the used IP address should be stored for the next start of AutoIP. 0 means do not keep the IP, 1 means keep the IP address for the next AutoIP start.</td>
</tr>
</tbody>
</table>

Return value

- 0   Ok. AutoIP stopped. IP address cleared.
- IP Ok. AutoIP stopped. The IP address (for example 0xA9FExxxx) has been kept.
- -1 Error. Illegal interface number.

Additional information

The function stops the AutoIP module. The IP address which was used during AutoIP was activated, can be kept to speed up the configuration process after reactivating AutoIP. If the IP address will not be kept, AutoIP creates a new IP address after the reactivation.
13.2.3  IP_AutoIP_SetUserCallback()

Description
This function allows the caller to set a callback for an interface. The callback is called with every status change.

Prototype
void IP_AutoIP_SetUserCallback(unsigned IFaceId, IP_AUTOIP_INFORM_USER_FUNC * pfInformUser);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pfInformUser</td>
<td>Pointer to a user function of type IP_AUTOIP_INFORM_USER_FUNC which is called when a status change occurs.</td>
</tr>
</tbody>
</table>

Additional information
This mechanism is provided so that the caller can do some processing when the interface is up (like doing initializations or blinking LEDs, etc.).

IP_AUTOIP_INFORM_USER_FUNC is defined as follows:

typedef void (IP_AUTOIP_INFORM_USER_FUNC)(U32 IFaceId, U32 Status);
13.2.4 IP_AutoIP_SetStartIP()

Description
Sets the IP address which will be used for the first configuration try.

Prototype

```c
void IP_AutoIP_SetStartIP(unsigned IFaceId, U32 IPAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero based interface index.</td>
</tr>
<tr>
<td>IPAddr</td>
<td>4-byte IPv4 address.</td>
</tr>
</tbody>
</table>

Additional information

A call of this function is normally not required, but in some cases it can be useful to set the IP address which should be used as starting point of the AutoIP functionality.
13.3 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the AutoIP module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

13.3.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP AutoIP module</td>
<td>approximately 1.1 kByte</td>
</tr>
</tbody>
</table>

13.3.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP AutoIP module</td>
<td>approximately 1.0 kByte</td>
</tr>
</tbody>
</table>

13.3.3 RAM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP AutoIP module</td>
<td>approximately 0.7 kByte</td>
</tr>
</tbody>
</table>
Chapter 14

Address Collision Detection

All functions which are required to add Address Collision Detection (ACD) to your application are described in this chapter.
14.1 embOS/IP ACD backgrounds

The embOS/IP ACD module allows the user specific configuration of the behavior if an IPv4 address collision is detected. This means that more than one host in the network is using the same IPv4 address at the same time. This is discovered sending ARP discover packets to find hosts with the same addresses in the network.
## 14.2 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_ACD_Activate()</td>
<td>Activates the address conflict detection (ACD) for the specified interface.</td>
</tr>
<tr>
<td>IP_ACD_Config()</td>
<td>Configures the address conflict detection (ACD) behavior for startup and in case of conflicts.</td>
</tr>
</tbody>
</table>
14.2.1   IP_ACD_Activate()

Description
Activates the address conflict detection (ACD) for the specified interface.

Prototype
int IP_ACD_Activate(unsigned IFace);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value
0         ACD activated and free IP found (does not mean the initial IP was good).
1         No IP address set when ACD was activated.

Additional information
Activating the address conflict detection module means that a hook into the ARP module of the stack will be activated that allows the user to take action if an IPv4 address conflict on the network has been discovered.

When the ACD module is started it will check if the currently used IP address is in conflict with any other host on the network by sending ARP probes to find hosts with the same IPv4 address.

To allow the user to take action on those conflicts it is necessary to use IP_ACD_Config() before activating ACD.

In embOS/IP debug builds terminal I/O output can be enabled. ACD outputs status information in the terminal I/O window if the stack is configured to so (IP_MTYPE_ACD added to the log filter mask). Please refer to IP_SetLogFilter on page 1173 and IP_AddLogFilter on page 1171 for further information about the enabling terminal I/O.
14.2.2 IP_ACD_Config()

Description
Configures the address conflict detection (ACD) behavior for startup and in case of conflicts.

Prototype

```c
void IP_ACD_Config( unsigned IFace,
                     unsigned ProbeNum,
                     unsigned DefendInterval,
                     const ACD_FUNC * pACDContext );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>ProbeNum</td>
<td>Number of ARP probes to send upon activating ACD before declaring the actual used IP address to be free to be used.</td>
</tr>
<tr>
<td>DefendInterval</td>
<td>Interval in which the currently active IP address is being known as defended after taking action.</td>
</tr>
<tr>
<td>pACDContext</td>
<td>Pointer to a structure of type ACD_FUNC.</td>
</tr>
</tbody>
</table>
14.3 Data structures

14.3.1 Structure ACD_FUNC

Description
Used to store function pointers to the user defined callbacks to take several actions upon detecting an IP address conflict.

Prototype

```c
typedef struct {
    U32 (*pfRenewIPAddr)(unsigned IFace);
    int (*pfDefend)(unsigned IFace);
    int (*pfRestart)(unsigned IFace);
} ACD_FUNC;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfRenewIPAddr</td>
<td>Function pointer to a user defined routine that is used to generate a new IPv4 address if there is a collision detected during ACD activation.</td>
</tr>
<tr>
<td>pfDefend</td>
<td>Function pointer to a user defined routine that is used to let the user implement his own defend strategy. Can be NULL.</td>
</tr>
<tr>
<td>pfRestart</td>
<td>Function pointer to a user defined routine that should reconfigure the IP address used by the stack and optionally re-activates ACD.</td>
</tr>
</tbody>
</table>
14.4 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the AutoIP module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

14.4.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP ACD module</td>
<td>approximately 0.4 kByte</td>
</tr>
</tbody>
</table>

14.4.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP ACD module</td>

</tr>
</tbody>
</table>
Chapter 15

UPnP (Add-on)

The embOS/IP implementation of UPnP which stand for Universal Plug and Play is an optional extension to embOS/IP. It allows making your target easily discoverable and advertising services available on your target throughout your network.
15.1 embOS/IP UPnP

The embOS/IP UPnP implementation is an optional extension which can be seamlessly integrated into your TCP/IP application. It combines the possibility to implemented UPnP services in a most flexible way by allowing to specify content to be sent upon UPnP requests completely generated by the application with a small memory footprint.

The UPnP module implements the relevant parts of the UPnP documentation released by the UPnP Forum.

<table>
<thead>
<tr>
<th>Document</th>
<th>Download</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application</td>
<td>Contains the example application to run the UPnP implementation with embOS/IP and embOS/IP Web server add-on.</td>
</tr>
<tr>
<td>IP</td>
<td>Contains the UPnP source file, IP_UPnP.c.</td>
</tr>
</tbody>
</table>
15.2 Feature list

- Low memory footprint.
- Advertising your services on the network
- Easy to implement
15.3 Requirements

TCP/IP stack

The embOS/IP UPnP implementation requires the embOS/IP TCP/IP stack and is designed to be used with the embOS/IP Web server add-on.
15.4 Backgrounds

UPnP is designed to provide services throughout a network without interaction of the user. It is designed to use standardized protocols such as IP, TCP, UDP, Multicast, HTTP and XML for communication and to distribute services provided by a device.

UPnP can be used to advertise services provided by a device across the network such as where to find the web interface for the device advertising. Newer operating systems support UPnP from scratch and will show UPnP devices available across a network and may provide easy access to a device by simply selecting the discovered UPnP device.

A typical usage would be to advertise media accessible on a media storage on the network and opening a file browser window to the resource upon opening the UPnP entry discovered.

15.4.1 Using UPnP to advertise your service in the network

The default UPnP XML file advertised is upnp.xml. A solution providing UPnP content has to serve a file called upnp.xml containing valid UPnP descriptors via a web server. The sample OS_IP_Webserver_UPnP.c provides a sample configuration for advertising a web server page that will open if the UPnP client clicks on the discovered UPnP device.

A discovered UPnP device will typically be shown in the network neighborhood of your operating system. A discovered device found by a Windows OS is shown in the picture below:

![Other Devices (2) SEGGER UPnP Demo](image)

The example below shows the most important excerpts from the OS_IP_Webserver_UPnP.c sample that are necessary to setup a UPnP device in your network.

```c
/* Excerpt from OS_IP_Webserver_UPnP.c */
//
// UPnP
//
#define UPNP_FRIENDLY_NAME     "SEGGER UPnP Demo"
#define UPNP_MANUFACTURER      "SEGGER Microcontroller GmbH and Co. KG" //
#define UPNP_MANUFACTURER_URL  "http://www.segger.com"
#define UPNP_MODEL_DESC        "SEGGER Web server with UPnP"
#define UPNP_MODEL_NAME        "SEGGER UPnP Demo"
#define UPNP_MODEL_URL         "http://www.segger.com/embos-ip-webserver.html"
```

The sample uses VFile hooks as described in IP_WEBS_AddVFileHook on page 647 to provide dynamically serving the necessary XML files for UPnP without the need for a real file system or further processing through the web server.

```c
/* Excerpt from OS_IP_Webserver_UPnP.c */
Thông tin

typedef  struct  {
    const  char      *  sFileName ;
    const  char      *  pData ;
    unsigned    NumBytes ;
}  VFILE_LIST ;

/* Excerpt from OS_IP_Webserver_UPnP.c */
Thông tin

typedef struct {
    const char * sFileName;
    const char * pData;
    unsigned  NumBytes;
} VFILE_LIST;
```

The example below shows the most important excerpts from the OS_IP_Webserver_UPnP.c sample that are necessary to setup a UPnP device in your network.
Several helper functions are provided in the sample to easily generate a valid XML file for advertising a service using UPnP.

/* Excerpt from Webserver_DynContent.c */

#define UPNP_FRIENDLY_NAME "SEGGER UPnP Demo"
#define UPNP_MANUFACTURER "SEGGER Microcontroller GmbH and Co. KG" // 's' is not allowed
#define UPNP_MANUFACTURER_URL "http://www.segger.com"
#define UPNP_MODEL_DESC "SEGGER Web server with UPnP"
#define UPNP_MODEL_NAME "SEGGER UPnP Demo"
#define UPNP_MODEL_URL "http://www.segger.com/embos-ip-webserver.html"

/* Excerpt from OS_IP_Webserver_UPnP.c */
/*****************************************************************************/

</thead>
<tbody>
<tr>
<td>IP_UPNP_Activate()</td>
<td>Activates UPnP by joining an <strong>IGMP</strong> group and advertising that we are now available with services.</td>
</tr>
</tbody>
</table>
15.5.1 IP_UPNP_Activate()

Description
Activates UPnP by joining an IGMP group and advertising that we are now available with services.

Prototype

```c
void IP_UPNP_Activate(unsigned IFace,
                        const char * acUDN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFace</td>
<td>Zero-base interface index.</td>
</tr>
<tr>
<td>acUDN</td>
<td>String containing a unique descriptor name. (Optional, can be NULL.)</td>
</tr>
</tbody>
</table>

Additional information

If `acUDN` is NULL the unique descriptor name will be generated from the HW addresse of the interface.
15.6 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the AutoIP module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

The pure size of the UPnP add-on has been measured as the size of the services provided may vary.

15.6.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>

<td>approximately 170 Bytes</td>
</tr>
</tbody>
</table>
The embOS/IP implementation of VLAN which stand for Virtual LAN allows separating your network into multiple networks without the need to separate it physically. This chapter will show you how easily VLAN access can be setup on your target.
16.1 embOS/IP VLAN

The embOS/IP VLAN implementation allows a fast and easy implement of VLAN on your target. embOS/IP VLAN support supports a basic VLAN tag specifying only a VLAN ID.
16.2 Feature list

- Low memory footprint.
- Easy to implement.
- Software based solution without the need for a driver to support VLAN tags.
16.3 Backgrounds

VLAN technology can be used to separate multiple devices operating on the same physical network into completely separated networks without seeing each other.

A typical usage would be to have 2 departments separated from each other but using the same infrastructure such as a shared switch or router. Only devices using the same VLAN ID will be able to see each other.

For this to happen 4 bytes are added in front of the packet type field in the Ethernet frame pushing the original packet type field back by 4 bytes. The Ethernet frame will still be of a maximum length 1518 bytes including CRC what means that instead of a maximum of 1500 bytes that can be transferred the amount of bytes that can be transferred per Ethernet frame will shrink to 1496 bytes per packet. VLAN tagged packets are typically forwarded by any switch as they are as the type field has been simply replaced and in most cases only the destination MAC, source MAC and packet type is checked. In this case the packet is simply of an unknown protocol and will be forwarded by the switch.

The picture below shows the structure of an Ethernet frame once without using a VLAN tag and once with using a VLAN tag being assigned to VLAN ID #2.
## 16.4 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IP_VLAN_AddInterface()</code></td>
<td>Adds a VLAN interface to the stack.</td>
</tr>
</tbody>
</table>
16.4.1 IP_VLAN_AddInterface()

Description
Adds a VLAN interface to the stack.

Prototype

```c
int IP_VLAN_AddInterface(unsigned HWIFace,
                        U16    VLANId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HWIFace</td>
<td>Zero-based index of an available network interface to be used as physical interface for the VLAN pseudo interface.</td>
</tr>
<tr>
<td>VLANId</td>
<td>12 bits VLAN ID that the new interface will recognize. The priority bits can be set here as well. They will be included when sending packets on this interface. The priority bits for received packets are ignored.</td>
</tr>
</tbody>
</table>

Return value

Zero-based index of the added VLAN interface.
16.5 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the AutoIP module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

Chapter 17

Tail Tagging (Add-on)

The embOS/IP support for the Micrel Tail Tagging feature that is available in many Micrel Switch PHYs is an optional extension to embOS/IP. It can be used to extend a typical single Ethernet port CPU with more full featured ports without having to redesign a complete hardware or even changing to a completely other CPU with more Ethernet ports. This chapter contains information about Tail Tagging and how to add it to your hardware and software.
17.1 embOS/IP Tail Tagging support

The embOS/IP Tail Tagging implementation is an optional extension which can be easily added to extend your hardware using a Micrel Switch PHY with Tail Tagging support instead of a single port PHY. It allows you to extend your single Ethernet port (also single Ethernet controller) CPU to as many ports that can be managed like a real network interface (Ethernet controller) in embOS/IP even with different hardware addresses.

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSP</td>
<td>Contains sample configurations for hardware that already uses embOS/IP Tail Tagging support.</td>
</tr>
<tr>
<td>IP</td>
<td>Contains the Tail Tagging sources, IP_MICREL_TAIL_TAGGING.c and the PHY driver for various Micrel Switch PHYs IP_PHY_MICREL_SWITCH.c.</td>
</tr>
</tbody>
</table>
17.2 Feature list

- Extend virtually any single port CPU to n manageable interfaces at low cost.
- Use the fast MII/RMII interface of your CPU and internal Ethernet controller instead of slower interfaces like SPI with external Ethernet controllers.
- Link status of each port can be monitored independent.
- Keep your existing design and known and preferred CPU.
- Each Tail Tagging interface can have its own hardware address.
- Low memory footprint.
- Seamless integration with the embOS/IP stack.
17.3 Use cases

The benefits of Tail Tagging are that it can be used to extend a single port Ethernet CPU to multiple, manageable physical ports where each port can be managed independently and can even have its own hardware address assign.

This can be used for various purposes when building hardware and software with special requirements. Some use cases are:

- Building a multihoming hardware that shall be fail safe on the network by providing multiple network paths that at the same time shall act as completely independent interfaces with full control.
- Building a low cost Router, Gateway or Bridge device interfacing multiple networks.
- Building a device that requires network separation features and at the same time is still able to use other techniques like VLAN/prioritizing via VLAN. VLAN can be used in a similar way than Tail Tagging but can not provide both features (VLAN and port separation) at the same time.
17.4 Requirements

The following requirements regarding software and hardware need to be met.

17.4.1 Software requirements

The embOS/IP Tail Tagging implementation requires the embOS/IP TCP/IP stack and a PHY driver for a Micrel Switch PHY that supports the Tail Tagging feature.

17.4.2 Hardware requirements

Of course a Micrel Switch PHY supporting Tail Tagging needs to be present on your hardware as well. The big advantage of using Tail Tagging instead of other methods like adding external Ethernet controllers is its simplicity that comes without any known downsides.

Single MAC unit CPU, single port design

The typical hardware design for an Ethernet capable hardware with the MAC unit inside the CPU is shown below. It consists of a CPU with a single internal MAC unit connected to an external single port PHY that can interface one port to the network.

The Ethernet data is transferred between MAC and PHY while the MDIO interface (typically also accessed via registers of the MAC) is used to access the PHY to configure it and periodically check the link status.

Single MAC unit CPU, switch PHY with Tail Tagging design

For Tail Tagging only a few simple changes to the hardware are necessary. The main difference is that configuration is no longer done via the MDIO interface but instead is done using an extra interface like SPI or SMI. This is due to a restricted set of registers that are available via the MDIO standard.

Typically the same registers that can be accessed via MDIO can be accessed via SPI or SMI as well, along many other registers not available via MDIO.

Using a Switch PHY with Tail Tagging not only allows you to connect multiple hosts but also allows you to fully control each external port/connector like it would be an additional expensive and external Ethernet controller.
17.5 Backgrounds

The Tail Tagging feature available in many Micrel Switch PHYs is a clever way to pass information between the PHY and the TCP/IP stack on which port of the Switch a packet has been received or to which port(s) it should be delivered when the TCP/IP stack sends data to the network.

Contents of a Tail Tagging frame

The picture below shows the content of a frame that is received from the Switch in the host or is sent from the host to the Switch.

![Frame received/sent from/to the PHY with Tail Tagging](image)

Regular Ethernet data (typical up to 1514 bytes) | Tail Tagging byte | Ethernet frame checksum

When the Switch has the Tail Tagging feature enabled all ports of the Switch will be used in this mode.

Receiving a frame with Tail Tagging

With Tail Tagging each Ethernet frame that is received will be added with a byte between the Ethernet data received in the frame and the checksum of the Ethernet frame itself. This step is unseen by the Ethernet controller as the frame checksum that is built by the sender above all the Ethernet data in the frame is altered by the PHY as well to represent the correct checksum of the original Ethernet data in the frame plus the byte that has been added. Due to the correct checksum the Ethernet controller does not have to be aware of Tail Tagging at all.

embOS/IP can then extract the information from which port the data has been received from the Tail Tagging byte and can assign the packet to the correct Tail Tagging interface in the system. The Tail Tagging byte is stripped in this process leaving only the original data that can then be transferred to upper layer protocols.

Sending a frame with Tail Tagging

Sending works similar than receiving a frame. Before the Ethernet frame is queued with the Ethernet controller for transmitting it to the PHY, a Tail Tagging byte is appended at the end of the data to send (and before the frame checksum if calculated and added by the Ethernet driver itself). This byte contains the information to which external PHY ports the packet shall be delivered and sent out to the network.

The whole process is again unseen by the Ethernet controller as it is only aware that the data to be sent is one byte more in total like if one byte more would be sent by an upper layer protocol.
17.6 Optimal MTU and buffer sizes

A Tail Tagging interface in embOS/IP is a virtual interface that uses a hardware interface for data transfer. As Tail Tagging requires to store one additional byte that is unknown to upper layer protocols the Tail Tagging byte is automatically subtracted from the MTU that has been configured for the hardware interface.

While simply using the original MTU - 1 is a safe and easy way it has the downside that the maximum MTU of an Ethernet packet is now 1499 bytes instead of 1500 bytes and might lead to slight fragmentation and small delays with hardware and other hosts that are optimized for MTUs of 1500 bytes.

To overcome this effect the MTU (and typically connected with it the size of the big packet buffers) in IP_X_Config() should not be configured to 1500 bytes but instead configured to 1501 bytes if it is known that Tail Tagging will be used.

If a mix of Tail Tagging and non Tail Tagging interfaces will be used (dual Ethernet controller in CPU, one using only single port and the other connected to a Switch using Tail Tagging) the MTU should be set accordingly for each of these interfaces using IP_SetMTU().
## 17.7 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>IP_MICREL_TAIL_TAGGING_AddInterface()</code></td>
<td>Adds a virtual interface to the stack using the Micrel Tail Tagging feature to separate switch ports.</td>
</tr>
</tbody>
</table>
**17.7.1 IP_MICREL_TAIL_TAGGING_AddInterface()**

**Description**
Add a virtual interface to the stack using the Micrel Tail Tagging feature to separate switch ports.

**Prototype**

```c
int IP_MICREL_TAIL_TAGGING_AddInterface(unsigned HWIFaceId, U8 InTag, U8 OutTag);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HWIFaceId</td>
<td>Zero-based interface index of the interface used as hardware interface.</td>
</tr>
<tr>
<td>InTag</td>
<td>Tag byte according to Micrel documentation to compare with an incoming (switch to target) Tail Tagging byte.</td>
</tr>
<tr>
<td>OutTag</td>
<td>Tag byte according to Micrel documentation to append for an outgoing (target to switch) packet on this interface. Multiple bits can be set to allow sending to multiple ports at the same time.</td>
</tr>
</tbody>
</table>

**Return value**

- ≥ 0 Interface index.
- < 0 Error.

**Example**

```c

****** End Of File ************************************************/
17.8 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the Tail Tagging module presented in the tables below have been measured on a Cortex-M4 system. Details about the further configuration can be found in the sections of the specific example.

17.8.1 ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V2.12, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP Tail Tagging</td>
<td>approximately 0.4 kByte</td>
</tr>
</tbody>
</table>

17.8.2 RAM usage

All required RAM is taken from the RAM that has been assigned to embOS/IP using IP_AddMemory(). Only a few bytes are required.
Chapter 18

WiFi support

embOS/IP WiFi support is an easy way to add the IEEE 802.11 standard also known as WiFi or WLAN to your project. It allows not only an easy start using WiFi in a new product but also allows adding WiFi support to existing projects already using embOS/IP interfaces like LAN, PPP, USBD RNDIS/ECM or any other in short time.

All functions that are required to add WiFi to your application and some background information about WiFi hardware that can be used with embOS/IP is described in this chapter.
18.1 embOS/IP WiFi support

The embOS/IP WiFi support allows adding different WiFi hardware in the same way as any other interface that can be added. The configuration and accessibility is bundled in an easy to understand API regardless of the underlying API of the WiFi hardware. This not only allows an easy start for adding WiFi to your project but comes in handy if you plan to exchange WiFi hardware in the future.
18.2 Feature list

- Unified API regardless of the WiFi module used.
- Easily add WiFi support as another interface to existing embOS/IP LAN solutions.
- No need for re-certification by using already WiFi certified modules.
- Access Point support (depends on the module).
- Protocol support not limited to protocols that are TCP/UDP based.
- Support for various host interfaces like UART/SPI/SDIO/RMII (depends on the module).
- Low memory footprint (embOS/IP WiFi software components).
- Seamless integration with the embOS/IP stack.
18.3 Requirements

Software requirements

The embOS/IP WiFi support requires the embOS/IP TCP/IP stack, the embOS/IP module (family) specific WiFi driver and typically a vendor SDK for the specific WiFi module (family).

The vendor SDK should feature a Hardware Abstraction Layer (HAL) that needs to be filled in with your interface specific hardware routines.

For WiFi modules that do not need an SDK, a HAL is provided by the embOS/IP WiFi module specific driver, allowing to interface to various host interfaces supported by the WiFi module.

Hardware requirements

The embOS/IP WiFi support can be used with virtually any module that is able to communicate with the host MCU and providing full Ethernet packet access. For communication with the host MCU typically an SPI interface is required. Other interfaces such as UART, SDIO, I2C or RMII might be supported by the module as well.

Different WiFi add-on boards for easy evaluation on the emPower eval board are available. The porting of the module specific hardware layer has already been done for these modules for the emPower eval board and are shipped with the drivers as example, can be found in the corresponding eval package.
18.4 Background information

This chapter does not cover the IEEE 802.11 standard as this would be too much information and required information about the standard itself can be easily found on the Internet. The background information referenced herein shall help to understand the level of implementation the embOS/IP WiFi support offers.

18.4.1 Definition of a WiFi module

A WiFi module typically describes a small form factor board that basically consists of two components:

- An RF (Radio Frequency) module
- A companion MCU

WiFi modules are in fact external (Ethernet) controllers. The companion MCU is used to interface the RF module to actually establish WiFi communication. This is controlled by providing vendor specific commands to the companion MCU from the host MCU using one of the supported host interfaces of the WiFi module.

As each vendor is using its own command set, there is no common API that can be used across different modules, at least not between different vendors. Typically command sets are kept compatible within a product family of a vendor. This makes various modules compatible with the same SDK provided from the vendor.

Typically WiFi modules come with their own TCP/IP stack on board. This makes them easy to use for smaller projects like a weather station that periodically sends its data to a server. While these internal TCP/IP stacks might already come with some features like a small web server, they are also limited to the features of the built-in commands and protocols.

Benefits of using WiFi modules

18.4.2 Benefits of using WiFi modules

While the WiFi circuitry could be directly integrated with your PCB there are various benefits from using an available WiFi module instead of your own implementation:

- No re-certification: Typically the WiFi modules available are already certified by the WiFi Alliance. This saves a lot of time and costs otherwise spent for a certification process of your own designed WiFi circuitry.
- Using a design that has proven to be working.
- Easy to evaluate/no need for prototyping in regards to the WiFi circuitry.
- Can easily extend existing solutions using a free standard peripheral interface like SPI without redesigning the whole hardware.
- Offloading crypto operations necessary for encryption like WPA2 to the companion MCU.

Besides the hardware designing and evaluation aspects, the biggest benefit is without doubt the elimination of a re-certification process which might be time and cost intensive. Typically the modules are completely certified when using an integrated antenna or are certified when being used with a selection of one or more antennas specified by the module vendor.

18.4.3 Module internal vs. external TCP/IP stack

While most WiFi modules come with their own internal TCP/IP stack on the companion MCU, they are typically limited in usage to their built-in commands. This usually means only having access to a limited amount of TCP and UDP sockets that can be used to implement higher level protocols based on these two base protocols.

While only having a limited amount of TCP and UDP sockets might be enough for some small projects, this concept lacks control and extensibility. To allow more control and extensibility an external TCP/IP stack like embOS/IP needs to be used. This allows having control over the complete Ethernet frame of the packet to implement protocols on a lower level such as ARP or VLAN.
It is often referred to as pass-through-mode or bypass-mode to give an external stack full control over the whole Ethernet frame. It disables the processing by the module internal TCP/IP stack and exchanges the complete Ethernet frame with the TCP/IP stack on the host MCU.

18.4.4 Supported WiFi modules

The intention of WiFi support for embOS/IP is to allow extending an already established product with WiFi in a flexible and easy way. At the same time it shall be an easy to use solution for new projects. Features shall not depend on module features in the first place and shall be extensible at any time. embOS/IP supports only modules that are able to exchange complete Ethernet frames with the host MCU using a so called pass-through-mode or bypass-mode to fulfill this goal.

Being able to access the whole Ethernet frame, embOS/IP is not only able to use TCP and UDP based high level protocols but allows low level protocols via WiFi as well. Using this solution, existing and future add-ons can be used via WiFi the same way they would be with a cable based solution.
### 18.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WIFI_AddAssociateChangeHook()</td>
<td>Adds a function to the IP_HOOK_ON_WIFI_ASSOCIATE_CHANGE list.</td>
</tr>
<tr>
<td>IP_WIFI_AddClientNotificationHook()</td>
<td>Adds a function to the IP_HOOK_ON_WIFI_CLIENT_NOTIFICATION list.</td>
</tr>
<tr>
<td>IP_WIFI_AddInterface()</td>
<td>Adds a WiFi interface to the stack.</td>
</tr>
<tr>
<td>IP_WIFI_AddIsrExecDoneHook()</td>
<td>Adds a callback that gets executed at the end of the WiFi interrupt handling.</td>
</tr>
<tr>
<td>IP_WIFI_AddSignalChangeHook()</td>
<td>Adds a function to the IP_HOOK_ON_WIFI_SIGNAL_CHANGE list.</td>
</tr>
<tr>
<td>IP_WIFI_ConfigAllowedChannels()</td>
<td>Configures the channels that are allowed to be used for network scan and associate requests.</td>
</tr>
<tr>
<td>IP_WIFI_ConfigIsrTaskAlwaysSignaled()</td>
<td>Keeps the interface in signaled state to be polled each time regardless if there really was a signal or not.</td>
</tr>
<tr>
<td>IP_WIFI_ConfigIsrTaskTimeout()</td>
<td>Sets the timeout [ms] after which the WiFi ISR Task polls the driver interrupt routine even if it has not been signaled.</td>
</tr>
<tr>
<td>IP_WIFI_Connect()</td>
<td>Connects to a selected SSID or starts as access point.</td>
</tr>
<tr>
<td>IP_WIFI_Disconnect()</td>
<td>Disconnects from any connected network or stops the access point mode.</td>
</tr>
<tr>
<td>IP_WIFI_IsrExec()</td>
<td>Executes the interrupt routine of the driver once.</td>
</tr>
<tr>
<td>IP_WIFI_IsrTask()</td>
<td>Polls the ISR routine of the driver once it has been signaled to do so e.g.</td>
</tr>
<tr>
<td>IP_WIFI_Scan()</td>
<td>Scans for available wireless networks.</td>
</tr>
<tr>
<td>IP_WIFI_Security2String()</td>
<td>Converts the numeric security value to a readable text.</td>
</tr>
<tr>
<td>IP_WIFI_SignalIsrTask()</td>
<td>Signals the WiFi ISR task to poll the interrupt routine of the driver.</td>
</tr>
</tbody>
</table>
18.5.1 IP_WIFI_AddAssociateChangeHook()

Description
Adds a function to the IP_HOOK_ON_WIFI_ASSOCIATE_CHANGE list.

Prototype

```c
void IP_WIFI_AddAssociateChangeHook(IP_HOOK_ON_WIFI_ASSOCIATE_CHANGE * pHook,
                                   IP_WIFI_pfOnAssociateChange       pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to hook structure to link.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to function to call on change.</td>
</tr>
</tbody>
</table>
18.5.2 IP_WIFI_AddClientNotificationHook()

Description

Adds a function to the IP_HOOK_ON_WIFI_CLIENT_NOTIFICATION list. This list is notified when a client connects or disconnect when in access point mode.

Prototype

```c
void IP_WIFI_AddClientNotificationHook(IP_HOOK_ON_WIFI_CLIENT_NOTIFICATION * pHook,
                                       IP_WIFI_pfOnClientNotification        pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to hook structure to link.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to function to call on notification.</td>
</tr>
</tbody>
</table>
18.5.3 IP_WIFI_AddInterface()

Description
Adds a WiFi interface to the stack.

Prototype

```c
int IP_WIFI_AddInterface(const IP_HW_DRIVER * pDriver);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDriver</td>
<td>Pointer to IP_HW_DRIVER API table.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥ 0</td>
<td>Interface ID of the new interface.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>
18.5.4   IP_WIFI_AddIsrExecDoneHook()

**Description**
Add a callback that gets executed at the end of the WiFi interrupt handling.

**Prototype**
```c
void IP_WIFI_AddIsrExecDoneHook (unsigned IFaceId, IP_HOOK_ON_WIFI_ISR_EXEC_DONE * pHook, IP_WIFI_pfOnIsrExecDone pf);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pHook</td>
<td>Pointer to hook structure to link.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to function to call on change.</td>
</tr>
</tbody>
</table>

**Additional information**
A callback that signals the end of the ISR handler routine is required when using level sensitive interrupts that only signal a task like the WiFi ISR task to run. The following example demonstrates why this is necessary:
1. Interrupt line gets high.
2. Level sensitive interrupt is fired.
3. Signaling the WiFi ISR task to run.
4. Clearing the interrupt pending flag (could have been done before 3. as well).
5. The interrupt is still pending as typically the interrupt line on WiFi modules only gets low after all messages have been received. For this the WiFi ISR Task would need to run but we are stuck at 2. as the level sensitive interrupt constantly fires.

**Solution:**
After 2. simply disable the interrupt. Once all messages we are aware of have been processed the WiFi ISR task will run to wait until it is signaled again. Before actually waiting the callback gets executed telling us that now is the right moment to clear the pending interrupt flag and re-enabling the interrupt itself as most likely the interrupt line is now low and we are not instantly back in the interrupt. Of course it might happen that we are almost instantly back the interrupt as new messages are ready at the module to be received.
18.5.5  IP_WIFI_AddSignalChangeHook()

Description
Adds a function to the IP_HOOK_ON_WIFI_SIGNAL_CHANGE list.

Prototype

```c
void IP_WIFI_AddSignalChangeHook(IP_HOOK_ON_WIFI_SIGNAL_CHANGE * pHook,
                                IP_WIFI_pfOnSignalChange        pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to hook structure to link.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to function to call on change.</td>
</tr>
</tbody>
</table>
18.5.6   IP_WIFI_ConfigAllowedChannels()

Description
Configures the channels that are allowed to be used for network scan and associate requests.

Prototype

```c
int IP_WIFI_ConfigAllowedChannels(       unsigned    IFaceId,
                                        const  U8       *  paChannel,
                                        U8         NumChannels );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>paChannel</td>
<td>Pointer to a list of allowed channels.</td>
</tr>
<tr>
<td>NumChannels</td>
<td>Number of channels in list.</td>
</tr>
</tbody>
</table>

Return value

- = 0       O.K.
- ≠ 0       Error.

Additional information

Allowed channels are a subset of the configured regulatory domain.
18.5.7  **IP_WIFI_ConfigIsrTaskAlwaysSignaled()**

**Description**

Keeps the interface in signaled state to be polled each time regardless if there really was a signal or not.

**Prototype**

```c
void  IP_WIFI_ConfigIsrTaskAlwaysSignaled(unsigned IFaceId, char OnOff);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0 : Off.  
|           | • Other: On. |
18.5.8 IP_WIFI_ConfigIsrTaskTimeout()

Description
Sets the timeout [ms] after which the WiFi ISR Task polls the driver interrupt routine even if it has not been signaled.

Prototype

```c
void IP_WIFI_ConfigIsrTaskTimeout(unsigned IFaceId, 
                                 U32 Timeout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout [ms].</td>
</tr>
</tbody>
</table>
18.5.9  IP_WIFI_Connect()

Description
Connects to a selected SSID or starts as access point.

Prototype

```c
int IP_WIFI_Connect(       unsigned                  IFaceId,
                          const  IP_WIFI_CONNECT_PARAMS *  pParams,
                          U32                      Timeout );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pParams</td>
<td>Pointer to structure that contains connection parameters.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout before considering connect attempt failed [ms].</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
≠ 0  Error.
18.5.10  IP_WIFI_Disconnect()

Description
Disconnects from any connected network or stops the access point mode.

Prototype

```c
int IP_WIFI_Disconnect(unsigned IFaceId,
                        U32       Timeout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout before considering disconnect attempt failed [ms].</td>
</tr>
</tbody>
</table>

Return value

- = 0  O.K.
- ≠ 0  Error.
18.5.11   IP_WIFI_IsrExec()

Description
Executes the interrupt routine of the driver once.

Prototype

void IP_WIFI_IsrExec(unsigned IFaceId);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface ID.</td>
</tr>
</tbody>
</table>
18.5.12  IP_WIFI_IsrTask()

Description
Polls the ISR routine of the driver once it has been signaled to do so e.g. from an external interrupt.

Prototype

```c
void IP_WIFI_IsrTask(void);
```

Additional information
Waits in a loop for the next signal (with or without timeout). Needs to have highest task priority of all IP tasks including IP_RxTask().
18.5.13 IP_WIFI_Scan()

Description
Scans for available wireless networks.

Prototype

```c
int IP_WIFI_Scan(unsigned IFaceId, U32 Timeout, IP_WIFI_pfScanResult pf, const char * sSSID, U8 Channel);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout before aborting the scan [ms].</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to be used for each single result.</td>
</tr>
<tr>
<td>sSSID</td>
<td>SSID to find. May be NULL to scan all available networks.</td>
</tr>
<tr>
<td>Channel</td>
<td>Selected channel to scan. 0 means all channels.</td>
</tr>
</tbody>
</table>

Return value

= 0 O.K.
≠ 0 Error.

Additional information

If an SSID to find has been set the result callback will report the connection parameters only for the selected SSID. Without a given SSID a list of available networks and their parameters will be returned.
18.5.14   IP_WIFI_Security2String()

Description
Converts the numeric security value to a readable text.

Prototype

```
char *IP_WIFI_Security2String(U8 Security);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security</td>
<td>Numeric security value.</td>
</tr>
</tbody>
</table>

Return value

Pointer to string of the security.
18.5.15  IP_WIFI_SignalIsrTask()

Description
Signals the WiFi ISR task to poll the interrupt routine of the driver.

Prototype

```c
void IP_WIFI_SignalIsrTask(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface ID.</td>
</tr>
</tbody>
</table>
## 18.6 Data structures

<table>
<thead>
<tr>
<th>Structure / Callback</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WIFI_CONNECT_PARAMS</td>
<td>Used to configure parameters for connecting to an Access Point or starting your own Access Point.</td>
</tr>
</tbody>
</table>
18.6.1 Structure IP_WIFI_CONNECT_PARAMS

Description

Used to configure parameters for connecting to an Access Point or starting your own Access Point.

Prototype

```c
typedef struct {
    const char*             sSSID;
    const char*             sWPAPass;
    const IP_WIFI_WEP_KEY*  paWEPKey;
    U8                     abBSSID[6];
    U8                     NumWEPKeys;
    U8                     WEPActiveKeyId;
    U8                     Mode;
    U8                     Security;
    U8                     Channel;
} IP_WIFI_CONNECT_PARAMS;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sSSID</td>
<td>SSID to connect to or to open when in Access point mode.</td>
</tr>
<tr>
<td>sWPAPass</td>
<td>WPA(2) passphrase to use.</td>
</tr>
<tr>
<td>paWEPKey</td>
<td>Array of pointers to binary WEP keys.</td>
</tr>
<tr>
<td>abBSSID</td>
<td>HW address of the access point to connect to.</td>
</tr>
<tr>
<td>NumWEPKeys</td>
<td>Number of WEP keys configured in paWEPKey.</td>
</tr>
<tr>
<td>WEPActiveKeyId</td>
<td>0..3: Index of WEP key to be used for sending, typically index 0.</td>
</tr>
<tr>
<td>Mode</td>
<td>IP_WIFI_MODE_INFRASTRUCTURE or IP_WIFI_MODE_ACCESS_POINT (if supported by the driver and module).</td>
</tr>
<tr>
<td>Security</td>
<td>Security used or security to use if we are starting an Access Point. IP_WIFI_SECURITY_OPEN or IP_WIFI_SECURITY_WEP_SHARED or IP_WIFI_SECURITY_WPA_TKIP or IP_WIFI_SECURITY_WPA_AES or IP_WIFI_SECURITY_WPA_WPA2_MIXED or IP_WIFI_SECURITY_WPA2_AES.</td>
</tr>
<tr>
<td>Channel</td>
<td>Channel to use for connect or starting an Access Point. When connecting 0 means any.</td>
</tr>
</tbody>
</table>
embOS/IP has been designed to cooperate with any kind of hardware. To use specific hardware with embOS/IP, a so-called network interface driver for that hardware is required. The network interface driver consists of basic functions for accessing the hardware and a global table that holds pointers to these functions.
19.1 Network interface drivers general information

To use embOS/IP, a network interface driver matching the target hardware is required. The code size of a network interface driver depends on the hardware and is typically between 1 and 3 kBytes. The driver handles both the MAC (media access control) unit as well as the PHY (Physical interface). We recommend using drivers written and tested by SEGGER. However, it is possible to write your own driver. This is explained in section Writing your own driver on page 492.

The driver interface has been designed to allow support of internal and external Ethernet controllers (EMACs). It also allows to take full advantage of hardware features such as MAC address filtering and checksum computation in hardware.

19.1.1 MAC address filtering

The stack passes a list of MAC addresses to the driver. The driver is responsible for making sure that all packets from all MAC addresses specified are passed to the stack. It can do so with "precise filtering" if the hardware has sufficient filters for the given number of MAC addresses. If more MAC addresses are passed to the driver than hardware filters are available, the driver can use a hash filter if available in hardware or switch to promiscuous mode.

This is a very flexible solution which allows making best use of the hardware filtering capabilities on all known Ethernet controllers. It also allows simple implementations to simply switch to promiscuous mode.

19.1.2 Checksum computation in hardware

When the interface is initialized, the stack queries the capabilities of the driver. If the hardware can compute IP, TCP, UDP, ICMP checksums, it can indicates this to the stack. In this case, the stack does not compute these checksums, improving throughput and reducing CPU load.

19.1.3 Ethernet CRC computation

Every Ethernet packet includes a 32-bit trailing CRC. In most cases, the Ethernet controller is capable of computing the CRC. The drivers take advantage of this. The CRC is computed in the driver only if the hardware does not support CRC computation.
19.2 Available network interface drivers

Network interface drivers are optional components to embOS/IP. Network interface drivers are already available for popular hardware and a list could be found on our website https://www.segger.com/embosip-drivers.html.

19.2.1 Configuring the driver

The interface with the corresponding driver should be added to the configuration function IP_X_Config() with a call to IP_AddEtherInterface().

Depending on the hardware, it could be needed to configure the PHY mode for RMII with IP_NI_ConfigPHYMode(). As the default configuration is MII, the call is optional and requested only to use RMII.

Some drivers provides also configuration functions, for example to configure the number of buffer used, specify registers base address, ...

19.2.2 BSP configuration

Drivers are calling BSP function in order to configure hardware access:

- Old driver are using functions like BSP_ETH_Init() and BSP_ETH_InstallISR() which are implemented in BSP.c.
- New and updated drivers are using the structure BSP_IP_API implemented in BSP_IP.c. See Structure BSP_IP_API on page 252 for more details. This structure needs to be set as BSP access API with the function IP_BSP_SetAPI().

19.2.3 Driver configuration example

The following code is an excerpt of IP_X_Config(). Reference to IP_X_Config on page 527 for a complete example.

```c
IFaceId = IP_AddEtherInterface(DRIVER);  // Add driver for your hardware.
IP_BSP_SetAPI(IFaceId, &BSP_IP_Api);     // Set BSP callbacks for hardware access.
IP_SetHWAddrEx(IFaceId, (const U8*)HW_ADDR, 6);  // MAC addr.: Needs to be unique.
IP_NI_ConfigPHYMode(IFaceId, 1);          // Configure PHY Mode: 0: MII, 1: RMII .
```
19.3 Writing your own driver

If you are going to use embOS/IP with your own hardware, you may have to write your own network interface driver. This section describes which functions are required and how to integrate your own network interface driver into embOS/IP.

Note: We strongly recommend contacting SEGGER if you need to have a driver for a particular piece of hardware which is not yet supported. Writing a driver is a difficult task which requires a thorough understanding of Ethernet, MAC, and PHY.

19.3.1 Network interface driver structure

embOS/IP uses a simple structure with function pointers to call the appropriate driver function for a device. Use the supplied template IP_NI_Template.c for the implementation.

Data structure

```c
typedef struct {
  int    (* pfInit )              ( unsigned  Unit);
  int    (* pfSendPacket )        ( unsigned  Unit);
  int    (* pfGetPacketSize )     ( unsigned  Unit);
  int    (* pfReadPacket )        ( unsigned  Unit ,  U8 *  pDest ,  unsigned  NumBytes);
  void   (* pfTimer )             ( unsigned  Unit);
  int    (* pfControl )           ( unsigned  Unit ,  int  Cmd ,  void  *  p);
  void   (* pfEnDisableRxInt )    ( unsigned  Unit ,  unsigned  OnOff);
}  IP_HW_DRIVER;
```

Elements of IP_HW_DRIVER

<table>
<thead>
<tr>
<th>Element</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfInit</td>
<td>Pointer to the initialization function.</td>
</tr>
<tr>
<td>pfSendPacket</td>
<td>Pointer to the send packet function.</td>
</tr>
<tr>
<td>pfGetPacketSize</td>
<td>Pointer to the get packet size function.</td>
</tr>
<tr>
<td>pfReadPacket</td>
<td>Pointer to the read packet function.</td>
</tr>
<tr>
<td>pfTimer</td>
<td>Optional: Pointer to the timer function. The routine is called from the stack periodically</td>
</tr>
<tr>
<td>pfControl</td>
<td>Pointer to the control function.</td>
</tr>
<tr>
<td>pfEnDisableRxInt</td>
<td>Optional: Pointer to enable/disable Rx interrupts.</td>
</tr>
</tbody>
</table>

Example

```c
/* Sample implementation taken from the driver for FREESCALE Kinetis */

/*********************************************************************
*       Driver API Table
* *********************************************************************/

const IP_HW_DRIVER IP_Driver_Kinetis = {
  _Init,
  _SendPacketIfTxIdle,
  _GetPacketSize,
  _ReadPacket,
  _Timer,
  _Control,
  _EnDisableRxInt
};
```
19.3.2 Device driver functions

This section provides descriptions of the network interface driver functions required by embOS/IP. Note that the names used for these functions are not really relevant for embOS/IP because the stack accesses them through a structure of function pointers.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Init()</td>
<td>General initialization function of the driver.</td>
</tr>
<tr>
<td>_SendPacketIfTxIdle()</td>
<td>Send the next packet in the send queue if transmitter is idle.</td>
</tr>
<tr>
<td>_GetPacketSize()</td>
<td>Reads buffer descriptors to find out if a packet has been received.</td>
</tr>
<tr>
<td>_ReadPacket()</td>
<td>Reads the first packet in the buffer.</td>
</tr>
<tr>
<td>_Timer()</td>
<td>Timer function called by the networking task, IP_Task(), once per second.</td>
</tr>
<tr>
<td>_Control()</td>
<td>This function is used to implement additional driver specific control functions. It can be empty.</td>
</tr>
<tr>
<td>_EnDisableRxInt()</td>
<td>Utility function to enable or disable receive interrupts. It can be empty.</td>
</tr>
</tbody>
</table>

19.3.3 Driver template

The driver template IP_NI_TEMPLATE.c is supplied in the folder Sample\IP\Driver\Template\.

Example

```c
/*********************************************************************
*   (c) SEGGER Microcontroller GmbH & Co. KG                          *
*   The Embedded Experts                                            *
*   www.segger.com                                                   *
**********************************************************************
-------------------------- END-OF-HEADER -----------------------------

/***************************************************************************/
*/ End of file */
embOS/IP has been designed to cooperate with any kind of hardware. Typically almost any PHY is compatible with the embOS/IP generic PHY driver as almost all standard PHYs are compliant to the IEEE 802.3u standard which also defines the first 6 standard registers and their bits that are used by the generic PHY driver. However there are some PHYs that might require additional setup or do not comply with IEEE 802.3u as it is expected by the generic PHY driver. To use them, a so-called PHY driver for that hardware is required that is aware of how the specific PHY can be accessed.
20.1  PHY drivers general information

To use embOS/IP with a PHY that cannot be used with the generic PHY driver, a specific PHY driver matching the target hardware is required. The code size of a PHY driver depends on the hardware but is typically only requires a couple of hundred bytes.

The PHY driver interface has been designed to allow support of generic features like checking the link state as well as being able to extend each specific driver with unique features only available for a specific hardware.

20.1.1 When is a specific PHY driver required?

A specific PHY driver is typically not required for any standard PHY on the market. However it might be required for the following reasons:

- The PHY registers do not (fully) comply with the IEEE 802.3u standard for the six first registers.
- The PHY requires additional setup that cannot be provided using the reset hook of the generic PHY driver.
- A PHY or (managed) Switch PHY shall be used that includes multiple PHYs that shall be treated like autonomous PHYs for link checking on each port.
- Any other special solution that simply can not be covered by a generic PHY driver.
20.2 Available PHY drivers

embOS/IP comes with a generic PHY driver that fits virtually any standard single port PHY that is on the market. PHY drivers for devices that are not compatible to the IEEE 802.3u standard, require additional setup or special solutions are optional components to embOS/IP.

The following PHY drivers are available and described in detail with their API:

<table>
<thead>
<tr>
<th>PHY driver</th>
<th>Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generic driver</td>
<td>IP_PHY_Driver_Generic</td>
</tr>
<tr>
<td>Micrel Switch PHY driver</td>
<td>IP_PHY_Driver_Micrel_Switch_&lt;ProductName&gt;</td>
</tr>
<tr>
<td>Marvell 88E1111 Fiber PHY driver</td>
<td>IP_PHY_Driver_MARVELL_88E1111_Fiber</td>
</tr>
</tbody>
</table>

To add a PHY driver to embOS/IP, `IP_PHY_AddDriver()` should be called from within `IP_X_Config()` with the proper identifier. Refer to `IP_PHY_AddDriver` on page 167 for detailed information.

20.2.1 Generic driver

The embOS/IP generic PHY driver fits virtually any standard single port PHY that complies with the IEEE 802.3u standard and is the default driver that comes with embOS/IP and is used when no other PHY driver is added for an interface that requires PHY support.

**Note**

Even if a PHY complies with the IEEE 802.3u standard it might require additional handling that can not be provided by the generic PHY driver and therefore might require a specific PHY driver in this case.

**Resource usage**

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V2.12, size optimization.

<table>
<thead>
<tr>
<th>ROM</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>approximately 0.8KBytes</td>
<td>0K Bytes</td>
</tr>
</tbody>
</table>

All required RAM is taken from the RAM that has been assigned to embOS/IP using `IP_AdAddressMemory()`. Only a few bytes are required.

20.2.1.1 Generic PHY driver API functions

The table below lists the available API functions for this driver:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PHY_GENERIC_RemapAccess()</td>
<td>This function allows remapping the access routines of a PHY interface.</td>
</tr>
</tbody>
</table>
20.2.1.2  IP_PHY_GENERIC_RemapAccess()

Description
This function allows remapping the access routines of a PHY interface. An example would
be to use the access routines of interface #0 for interface #1 as well.

Prototype

```c
void IP_PHY_GENERIC_RemapAccess(unsigned IFaceId,
                                  unsigned AccessIFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index to assign an access API.</td>
</tr>
<tr>
<td>AccessIFaceId</td>
<td>Zero-based interface index from where to use the access</td>
</tr>
<tr>
<td></td>
<td>API.</td>
</tr>
</tbody>
</table>

Additional information

The purpose to use the same MDIO interface for multiple PHY interfaces is that there are
dual PHYs out there like the TI DP83849I that use only one MDIO interface and address
their internal dual PHY via the PHY addr.

It is only possible to remap from an already initialized interface to a new one which means
AccessIFaceId needs to be higher than IFaceId.
20.2.2  Micrel Switch PHY driver

Due to the nature of a Switch PHY it contains multiple ports that can not be handled in a generic way. Therefore a driver that is aware of the specific hardware is required. The embOS/IP PHY driver for Micrel Switch PHYs supports automatically starting the Switch engine (autostart is disabled if used with a management interface like SMI or SPI) and allows further specific configuration for various purposes.

 Supported devices

The following is a list of supported devices and their labels:

<table>
<thead>
<tr>
<th>PHY driver</th>
<th>Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>KSZ8794</td>
<td>IP_PHY_Driver_Micrel_Switch_KSZ8794[HostPort]</td>
</tr>
<tr>
<td>KSZ8863</td>
<td>IP_PHY_Driver_Micrel_Switch_KSZ8863[HostPort]</td>
</tr>
<tr>
<td>KSZ8895</td>
<td>IP_PHY_Driver_Micrel_Switch_KSZ8895[HostPort]</td>
</tr>
</tbody>
</table>

Resource usage

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V2.12, size optimization.

<table>
<thead>
<tr>
<th>ROM</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>approximately 0.2KBytes</td>
<td>0K Bytes</td>
</tr>
</tbody>
</table>

All required RAM is taken from the RAM that has been assigned to embOS/IP using IP_Ad-
dMemory(). Only a few bytes are required.

20.2.2.1  Micrel Switch PHY driver API functions

The table below lists the available API functions for this driver:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PHY_MICREL_SWITCH_AssignPortNumber()</td>
<td>This function assigns the physical switch port number to an interface.</td>
</tr>
</tbody>
</table>
| IP_PHY_MICREL_SWITCH_ConfigLearnDisable()            | This function can set the learn disable config for a specific port to en-
abled/disabled.                                                             |
| IP_PHY_MICREL_SWITCH_ConfigRxEnable()                | This function can set Rx (network to switch) for a specific port to en-
abled/disabled.                                                             |
| IP_PHY_MICREL_SWITCH_ConfigTailTagging()             | This function switches Tail Tagging on/off.                                 |
| IP_PHY_MICREL_SWITCH_ConfigTxEnable()                | This function can set Tx (switch to network) for a specific port to en-
abled/disabled.                                                             |
20.2.2.2 IP_PHY_MICREL_SWITCH_AssignPortNumber()

Description
This function assigns the physical switch port number to an interface.

Prototype

```c
void IP_PHY_MICREL_SWITCH_AssignPortNumber(unsigned IFaceId,
                                          unsigned Port);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Port</td>
<td>Zero-based physical port number on the switch.</td>
</tr>
</tbody>
</table>
20.2.2.3  IP_PHY_MICREL_SWITCH_ConfigLearnDisable()

Description
This function can set the learn disable config for a specific port to enabled/disabled.

Prototype

```c
void IP_PHY_MICREL_SWITCH_ConfigLearnDisable(unsigned IFaceId,
                                             unsigned OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0: Switch addr. learning for the port enabled.  
|           | • 1: Switch addr. learning for the port disabled. |
20.2.2.4  IP_PHY_MICREL_SWITCH_ConfigRxEnable()

Description
This function can set Rx (network to switch) for a specific port to enabled/disabled.

Prototype

```c
void IP_PHY_MICREL_SWITCH_ConfigRxEnable(unsigned IFaceId,
                                        unsigned OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>OnOff</td>
<td>• 0: Rx for the port disabled.</td>
</tr>
<tr>
<td></td>
<td>• 1: Rx for the port enabled.</td>
</tr>
</tbody>
</table>
## 20.2.2.5 IP_PHY_MICREL_SWITCH_ConfigTailTagging()

### Description

This function switches Tail Tagging on/off.

### Prototype

```c
void IP_PHY_MICREL_SWITCH_ConfigTailTagging(unsigned IFaceId,
                                          unsigned OnOff);
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>OnOff</td>
<td>• 0: Tail Tagging off.</td>
</tr>
<tr>
<td></td>
<td>• 1: Tail Tagging on.</td>
</tr>
</tbody>
</table>

### Additional information

Needs to be used with the interface of the host port of the switch.

It is enough to set it for one port of the switch as the bit to change is in a register that is shared between all ports.

Tail Tagging needs to be supported by the stack as well and a Tail Tagging aware interface has to be added to the stack.
20.2.2.6 **IP_PHY_MICREL_SWITCH_ConfigTxEnable()**

**Description**
This function can set Tx (switch to network) for a specific port to enabled/disabled.

**Prototype**

```c
void IP_PHY_MICREL_SWITCH_ConfigTxEnable(unsigned IFaceId,
                                          unsigned OnOff);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| OnOff     | • 0: Tx for the port disabled.  
            • 1: Tx for the port enabled. |
20.2.3 Marvell 88E1111 Fiber PHY driver

Although the Marvell 88E1111 PHY in copper mode is supported out of the box by the Generic driver on page 505, this PHY supports a Fiber mode as well. The Fiber mode requires a different handling and therefore requires a separate driver to handle this mode.

Resource usage

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V2.12, size optimization.

<table>
<thead>
<tr>
<th>ROM</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>approximately 0.8 kBytes</td>
<td>0K Bytes</td>
</tr>
</tbody>
</table>

All required RAM is taken from the RAM that has been assigned to embOS/IP using IP_Ad-
dMemory(). Only a few bytes are required.
Chapter 21

WiFi drivers

embOS/IP allows to easily add WiFi (IEEE 802.11) support to your project. Using one of the supported WiFi modules and available driver for it allows a WiFi interface to be added in nearly the same easy way as adding any other embOS/IP interface.

As almost each WiFi module uses a different API and a more or less complete documentation of it, integration can become very time consuming. The embOS/IP WiFi drivers provide an unified API to different WiFi modules that allows an easy integration into your project in short time.

This chapter lists drivers that require special configuration or come with their own extended API that allows a configuration beyond the regular embOS/IP API.
21.1 WiFi drivers general information

There are two different types of WiFi drivers used with embOS/IP:

- Network Interface WiFi drivers
- WiFi PHY bridges

Both types make use of the same API for your application but are different in their how they provide WiFi support in terms of their hardware.

21.1.1 Network Interface WiFi drivers

The typical form of an embOS/IP WiFi driver is used in the same way as a regular Network Interface (NI) driver. It basically works like an external Ethernet controller, typically using communication via a peripheral interface like SPI. Other common interfaces used are I2C, UART or SDIO.

To the stack itself, this is just another interface that is added like it would be for an integrated or external Ethernet controller.

Using a free peripheral interface, this solution can not only be used to build a new hardware but can be used to upgrade existing solutions with WiFi as well.

While providing WiFi support by the simple usage of a peripheral interface like SPI, often an SDK of the WiFi module vendor is required for communication with the module using vendor specific commands. In some cases using the WiFi modules of a vendor is even prohibited without the vendor SDK.

This type of driver is added to the stack like a regular driver by calling `IP_WIFI_AddInterface()`.

21.1.2 WiFi PHY bridges

Some WiFi solutions offer to convert a regular Ethernet device into a WiFi solution by providing a bridge device. For a regular cable-based setup, a copper cable PHY would be connected to the Ethernet MAC of the MCU (or an external MAC). Instead of the copper cable PHY, a WiFi bridge can be connected, replacing the PHY. These devices are providing a so-called MAC(of the MCU)-to-MAC(of the WiFi module) mode and are interfaced via (R)MII the same way as a regular PHY would be.

Ethernet communication takes place using (R)MII and therefore requires an Ethernet MAC to be present. A second configuration interface like SPI or UART is required as well as (R)MII is used for Ethernet data only.

Using this solution, an existing design can be converted to a WiFi solution by basically exchanging the PHY. The separation of the Ethernet data and configuration has the chance to reach higher transfer speeds than a single unidirectional interface handling Ethernet and configuration at the same time.

Like any other PHY driver, an Ethernet controller and its driver is still required. This means that first an Ethernet driver has to be added calling `IP_AddEtherInterface()` and then the driver of the WiFi PHY bridge has to be added and assigned to this interface by calling `IP_PHY_AddDriver()`.
21.2 List of special WiFi drivers

Several WiFi drivers are available for embOS/IP to provide an unified embOS/IP WiFi API to the vendor specific API. The vendor specific API is different between vendors and might even be different for modules from the same vendor. In general all drivers are added to the stack in the same way:

To add a WiFi driver to embOS/IP, IP_WIFI_AddInterface() should be called from within IP_X_Config() with the proper identifier.

To add a WiFi PHY bridge driver to embOS/IP, IP_PHY_AddDriver() on page 132 should be called from within IP_X_Config() with the proper identifier.

Depending on the module and driver they might require additional configuration or provide additional features. These additional configuration functions are listed here. The following WiFi drivers are described in detail with their API:

<table>
<thead>
<tr>
<th>WiFi drivers with special functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectOne IW</td>
</tr>
<tr>
<td>Redpine Signals RS9113</td>
</tr>
</tbody>
</table>
21.2.1 **ConnectOne IW**

The embOS/IP ConnectOne IW driver supports all WiFi<->LAN bridges sharing the same AT+i command set which basically are all WiFi modules named “iW-*” using the CO2144 or the older CO2128 core CPU.

21.2.1.1 **Hardware access abstraction**

The ConnectOne IW driver requires a hardware access API to be passed to IP_PHY_Ad-

A sample for a SPI connection is shipped with the driver as reference implementation.

```c
typedef struct {
  void  (* pfHWReset )       ( unsigned IFaceId);
  int   (* pfSendATCommand )( unsigned IFaceId, U32 Timeout , const char * sCmd);
  int   (* pfClrBuf )        ( unsigned IFaceId , U32 Timeout , char IgnoreSpiInt);
  int   (* pfLoadLine )      ( unsigned IFaceId , U32 Timeout);
  int   (* pfReadLine )      ( unsigned IFaceId , U32 Timeout , char* pBuffer,
                             unsigned BufferSize);
}  IP_PHY_WIFI_CONNECTONE_IW_ACCESS;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfHWReset</td>
<td>Reset the WiFi module. Shall only return after the module reset has been successfully asserted and deasserted. Only used in case of an error. The module shall be manually hardware reset once during startup.</td>
</tr>
<tr>
<td>pfSendATCommand</td>
<td>Sends the given AT+i command to the module. CR&amp;LF are included in the string to send.</td>
</tr>
<tr>
<td>pfClrBuf</td>
<td>Reads data from the module until SPI_INT gets deasserted. If IgnoreSpiInt is set the module could be in an unknown state after an error and the SPI_INT line might no longer be reliable. In this case just try to read data for some time to clear all data left in the module for a fresh start.</td>
</tr>
<tr>
<td>pfLoadLine</td>
<td>Reads in data in chunks as sent by the WiFi module until the buffer is full or a complete line is in the buffer. A static buffer is expected to be used to first assemble the chunks into a complete message.</td>
</tr>
<tr>
<td>pfReadLine</td>
<td>Checks if a complete line is in static buffer and copies it to the provided buffer.</td>
</tr>
</tbody>
</table>

21.2.1.2 **ConnectOne IW driver API functions**

The table below lists the available API functions for this driver:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PHY_WIFI_CONNECTONE_IW_ConfigSPI()</td>
<td>Sets the SPI_INT port the module uses to signal an event.</td>
</tr>
</tbody>
</table>
21.2.1.3  IP_PHY_WIFI_CONNECTONE_IW_ConfigSPI()

Description
Sets the SPI_INT port the module uses to signal an event.

Prototype

```c
void IP_PHY_WIFI_CONNECTONE_IW_ConfigSPI(unsigned IFaceId,
                                           char     SPIConfig);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>SPIConfig</td>
<td>SPI_INT port configuration as mentioned in the AT+i command documentation.</td>
</tr>
</tbody>
</table>
21.2.2 Redpine Signals RS9113

The embOS/IP Redpine Signals RS9113 driver supports the RS9113 Connect-io-n and WiseConnect family and modules compatible.

21.2.2.1 Redpine Signals RS9113 driver API functions

The table below lists the available API functions for this driver:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_NI_WIFI_REDPINE_RS9113_ConfigAntenna()</td>
<td>Selects the internal or external antenna and configures the gain for 2.4GHz and 5GHz modes.</td>
</tr>
<tr>
<td>IP_NI_WIFI_REDPINE_RS9113_ConfigRegion()</td>
<td>Selects a world region and allowed channel configuration.</td>
</tr>
<tr>
<td>IP_NI_WIFI_REDPINE_RS9113_SetSpiSpeedChangeCallback()</td>
<td>Sets a callback to be executed when the SPI interface can be used in high speed mode (above 25MHz) or when it is reset due to a module reset to recover from an error.</td>
</tr>
<tr>
<td>IP_NI_WIFI_REDPINE_RS9113_SetAccessPointParameters()</td>
<td>Configures access point parameters.</td>
</tr>
</tbody>
</table>
21.2.2.2  IP_NI_WIFI_REDPINE_RS9113_ConfigAntenna()

Description
Selects the internal or external antenna and configures the gain for 2.4GHz and 5GHz modes.

Prototype

```c
int  IP_NI_WIFI_REDPINE_RS9113_ConfigAntenna ( unsigned IFaceId,
           U8       Antenna,
           U8       Gain_24GHz,
           U8       Gain_5GHz );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>Antenna</td>
<td>• 0: Internal antenna</td>
</tr>
<tr>
<td></td>
<td>• 1: External antenna</td>
</tr>
<tr>
<td>Gain_24GHz</td>
<td>0..10 (according to RS9113 API documentation)</td>
</tr>
<tr>
<td>Gain_5GHz</td>
<td>0..10 (according to RS9113 API documentation)</td>
</tr>
</tbody>
</table>

Return value

= 0   O.K.
≠ 0   Error.

Additional information

The value that can be configured for the antenna gain is not explained in detail in the RS9113 API documentation. The values are passed to the module without modification.
21.2.2.3 IP_NI_WIFI_REDPINE_RS9113_ConfigRegion()

Description
Selects a world region and allowed channel configuration.

Prototype

```c
int IP_NI_WIFI_REDPINE_RS9113_ConfigRegion(unsigned IFaceId,
                                          U8     Region);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
| Region    | • IP_NI_WIFI_REDPINE_RS9113_REGION_AUTO_DETECT  
           • IP_NI_WIFI_REDPINE_RS9113_REGION_US  
           • IP_NI_WIFI_REDPINE_RS9113_REGION_EUROPE  
           • IP_NI_WIFI_REDPINE_RS9113_REGION_JAPAN  
           • IP_NI_WIFI_REDPINE_RS9113_REGION_WORLD |

Return value

= 0  O.K.
≠ 0  Error.

Additional information

Has to be called during init.

For a list of channels that are enabled for each region, please refer to the RS9113 API documentation and search for “Region_code”. 
21.2.2.4  IP_NI_WIFI_REDPINE_RS9113_SetSpiSpeedChangeCallback()

Description
Sets a callback to be executed when the SPI interface can be used in high speed mode (above 25MHz) or when it is reset due to a module reset to recover from an error.

Prototype

```c
void IP_NI_WIFI_REDPINE_RS9113_SetSpiSpeedChangeCallback
    (unsigned IFaceId, IP_NI_WIFI_REDPINE_RS9113_pfOnSpiSpeedChange pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to execute on a change.</td>
</tr>
</tbody>
</table>
21.2.2.5  IP_NI_WIFI_REDPINE_RS9113_SetAccessPointParameters()

Description  
Configures access point parameters. If not called, default values are used.

Prototype

```c
void IP_NI_WIFI_REDPINE_RS9113_SetAccessPointParameters
                      
(       unsigned                       IFaceId ,
     const  IP_NI_WIFI_RS9113_AP_CONFIG *  pParams );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pParams</td>
<td>Pointer on the parameters structure.</td>
</tr>
</tbody>
</table>

Additional information

For details on the parameters value refer to the RS9113 API documentation of the function `rsi_set_ap_config()`. 
embOS/IP can be used without changing any of the compile-time flags. All compile-time configuration flags are preconfigured with valid values, which match the requirements of most applications. Network interface drivers can be added at runtime.

The default configuration of embOS/IP can be changed via compile-time flags which can be added to IP_Conf.h. IP_Conf.h is the main configuration file for the TCP/IP stack.
22.1 Runtime configuration

Every driver folder includes a configuration file with implementations of runtime configuration functions explained in this chapter. These functions can be customized.
22.1.1 IP_X_Config()

Description
Helper function to prepare and configure the TCP/IP stack.

Prototype

```
void IP_X_Config(void);
```

Additional information
This function is called by the startup code of the TCP/IP stack from IP_Init(). Refer to IP_Init on page 153 for more information.

Example

```c
#include  "IP.h"
#include  "IP_NI_TEMPLATE.h"

#define  ALLOC_SIZE   0x6000
// Size of memory dedicated to the stack in bytes.
#define  DRIVER       & IP_Driver_Template
// Driver used for target.
#define  TARGET_NAME  "TARGET"
// Target name used for DHCP client.
#define  HW_ADDR      "\00\22\C7\FF\FF\FF"
// MAC addr. used for target.
#define  USE_DHCP     1
// Use DHCP client or static IP configuration.

// The following parameters are only used when the DHCP client is not active.

#define  IP_ADDR      IP_BYTES2ADDR(192, 168, 2, 252)
#define  SUBNET_MASK  IP_BYTES2ADDR(255, 255, 255, 0)
#define  GW_ADDR      IP_BYTES2ADDR(192, 168, 2, 1)
#define  DNS_ADDR     IP_BYTES2ADDR(192, 168, 2, 1)
```

```c
static  U32 _aPool [ ALLOC_SIZE / 4 ];
// This is the memory area used by the stack.
```
**CHAPTER 22**

**Runtime configuration**

```c
void IP_X_Config(void) {
    int mtu;
    int IFaceId;

    IP_AssignMemory(_aPool, sizeof(_aPool)); // Assigning memory should be the first thing.
    IFaceId = IP_AddEtherInterface(DRIVER); // Add driver for your hardware.
    IP_SetHWAddrEx(IFaceId, HW_ADDR, 6); // MAC addr.: Needs to be unique for production units.

    // Use DHCP client or define IP address, subnet mask,
    // gateway address and DNS server according to the
    // requirements of your application.
    
    #if USE_DHCP
    IP_DHCPC_Activate(IFaceId, TARGET_NAME, NULL, NULL); // Activate DHCP client.
    #else
    // your code for static configuration
    #endif
```

**Notes**

Typical memory/buffer configurations:

**Microcontroller system, minimum size optimized**

* `#define ALLOC_SIZE 0x1000`  // 4KBytes RAM.
* `mtu = 576;`  // 576 is minimum acc. to RFC,
  1500 is max. for Ethernet.
* `IP_SetMTU(0, mtu);`  // Maximum Transmission Unit is
  1500 for Ethernet by default.
* `IP_AddBuffers(4, 256);`  // Small buffers.
* `IP_AddBuffers(2, mtu + 16);`  // Big buffers. Size should be
  mtu + 16 byte for Ethernet header (2 bytes type, 2*6 bytes MAC, 2 bytes padding).
* `IP_ConfTCPSpace(2 * (mtu - 40), 1 * (mtu - 40));`  // Define the TCP Tx and Rx
  window size. At least Tx space for 2*(mtu-40) for two full TCP packets is needed.

**Microcontroller system, size optimized**

* `#define ALLOC_SIZE 0x3000`  // 12KBytes RAM.
* `mtu = 576;`  // 576 is minimum acc. to RFC,
  1500 is max. for Ethernet.
* `IP_SetMTU(0, mtu);`  // Maximum Transmission Unit is
  1500 for Ethernet by default.
* `IP_AddBuffers(8, 256);`  // Small buffers.
* `IP_AddBuffers(4, mtu + 16);`  // Big buffers. Size should be
  mtu + 16 byte for Ethernet header (2 bytes type, 2*6 bytes MAC, 2 bytes padding).
* `IP_ConfTCPSpace(2 * (mtu - 40), 2 * (mtu - 40));`  // Define the TCP Tx and Rx
  window size. At least Tx space for 2*(mtu-40) for two full TCP packets is needed.

**Microcontroller system, speed optimized or multiple connections**

* `#define ALLOC_SIZE 0x6000`  // 24 KBytes RAM.
* `mtu = 1500;`  // 576 is minimum acc. to RFC,
  1500 is max. for Ethernet.
* `IP_SetMTU(0, mtu);`  // Maximum Transmission Unit is
  1500 for Ethernet by default.
* `IP_AddBuffers(12, 256);`  // Small buffers.
* `IP_AddBuffers(6, mtu + 16);`  // Big buffers. Size should be
  mtu + 16 byte for Ethernet header (2 bytes type, 2*6 bytes MAC, 2 bytes padding).
* `IP_ConfTCPSpace(3 * (mtu - 40), 3 * (mtu - 40));`  // Define the TCP Tx and Rx
  window size. At least Tx space for 2*(mtu-40) for two full TCP packets is needed.

**System with lots of RAM**

* `#define ALLOC_SIZE 0x20000`  // 128 KBytes RAM.
* `mtu = 1500;`  // 576 is minimum acc. to RFC,
  1500 is max. for Ethernet.
* `IP_SetMTU(0, mtu);`  // Maximum Transmission Unit is
  1500 for Ethernet by default.
* `IP_AddBuffers(50, 256);`  // Small buffers.
* `IP_AddBuffers(50, mtu + 16);`  // Big buffers. Size should be
  mtu + 16 byte for Ethernet header (2 bytes type, 2*6 bytes MAC, 2 bytes padding).
* `IP_ConfTCPSpace(8 * (mtu - 40), 8 * (mtu - 40));`  // Define the TCP Tx and Rx
  window size. At least Tx space for 2*(mtu-40) for two full TCP packets is needed.
```
IP_SetAddrMaskEx (IFaceId, IP_ADDR, SUBNET_MASK); // Assign IP addr. and subnet mask.
IP_SetGWAddr (IFaceId, GW_ADDR); // Set gateway addr.
IP_DNS_SetServer (DNS_ADDR); // Set DNS server addr.
#endif

// Run-time configure buffers.
// The default setup will do for most cases.

mtu = 1500; // 576 is minimum acc. to RFC,
1500 is max. for Ethernet
IP_SetMTU (IFaceId, mtu); // Maximum Transmission Unit is
1500 for ethernet by default
IP_AddBuffers (12, 256); // Small buffers.
IP_AddBuffers (6, mtu + 16); // Big buffers. Size should be mtu +
16 byte for ethernet header (2 bytes type, 2*6 bytes MAC, 2 bytes padding)
IP_ConfTCP_Space (3 * (mtu-40), 3 * (mtu-40)); // Define the TCP Tx and Rx window size
IP_SOCKET_SetDefaultOptions (0); //
  | SO_TIMESTAMP // Send TCP timestamp to optimize the round trip time measurement. Normally not used in LAN.
  | SO_KEEPALIVE // Enable keepalives by default for TCP sockets.
  );

// Define log and warn filter.
// Note: The terminal I/O emulation might affect the timing of your
// application, since most debuggers need to stop the target
// for every terminal I/O output unless you use another
// implementation such as DCC or SWO.

IP_SetWarnFilter (0xFFFFFFFF); // 0xFFFFFFFF: Do not filter: Output all warnings.
IP_SetLogFilter (0 |
  IP_MTYPE_APPLICATION // Output application messages.
  IP_MTYPE_INIT // Output all messages from init.
  IP_MTYPE_LINK_CHANGE // Output a message if link status changes.
  IP_MTYPE_PPP // Output all PPP/PPPoE related messages.
  IP_MTYPE_DHCP // Output general DHCP status messages.
  //                  | IP_MTYPE_DHCP_EXT // Output additional DHCP messages.
  //                  | IP_MTYPE_CORE // Output log messages from core module.
  //                  | IP_MTYPE_DRIVER // Output log messages from driver.
  //                  | IP_MTYPE_ARP // Output log messages from ARP layer.
  //                  | IP_MTYPE_IP // Output log messages from IP layer.
  //                  | IP_MTYPE_TCP_CLOSE // Output a log messages if a TCP connection has been closed.
  //                  | IP_MTYPE_TCP_OPEN // Output a log messages if a TCP connection has been opened.
  //                  | IP_MTYPE_TCP_IN // Output TCP input logs.
  //                  | IP_MTYPE_TCP_OUT // Output TCP output logs.
  //                  | IP_MTYPE_TCP_RTT // Output TCP round trip time (RTT) logs.
  //                  | IP_MTYPE_TCP_RWIN // Output TCP RX window related log messages.
  //                  | IP_MTYPE_UDP // Output UDP related messages.
  //                  | IP_MTYPE_UDP_IN // Output UDP input logs.
  //                  | IP_MTYPE_UDP_OUT // Output UDP output logs.
  //                  | IP_MTYPE_UDP // Output all UDP related messages.
  //                  | IP_MTYPE_ICMP // Output ICMP related log messages.
  //                  | IP_MTYPE_NET_IN // Output network input related messages.
  //                  | IP_MTYPE_NET_OUT // Output network output related messages.
  //                  | IP_MTYPE_DNS // Output all DNS related messages.
  //                  | IP_MTYPE_SOCKET_STATE // Output socket status messages.
  //                  | IP_MTYPE_SOCKET_READ // Output socket read related messages.
  //                  | IP_MTYPE_SOCKET_WRITE // Output socket write related messages.
  //                  | IP_MTYPE_SOCKET // Output all socket related messages.
  );

// Add protocols to the stack.
IP_TCP_Add();
IP_UDP_Add();
IP_ICMP_Add();
#if IP_SUPPORT_IPV6
IP_IPV6_Add (IFaceId);
#endif
22.1.2 Driver handling

IP_X_Config() is called at initialization of the TCP/IP stack. It is called by the IP stack during IP_Init(). IP_X_Config() should help to bundle the process of adding and configuring the driver.

22.1.3 Memory and buffer assignment

The total memory requirements of the TCP/IP stack can basically be computed as the sum of the following components:

<table>
<thead>
<tr>
<th>Description</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP-Stack core app.</td>
<td>200 bytes</td>
</tr>
<tr>
<td>Sockets</td>
<td>n * app. 200 bytes</td>
</tr>
<tr>
<td>UDP connection</td>
<td>n * app. 100 bytes</td>
</tr>
<tr>
<td>TCP/ connection</td>
<td>n * app. 200 bytes + RAM for TCP Window</td>
</tr>
</tbody>
</table>

22.1.3.1 RAM for TCP window

The data for the TCP window is stored in packet buffers. The number of packet buffers required for best performance per socket is typically:

\[(\text{WindowSize} / \text{PacketBufferSize})\]

This amount of buffers (and RAM for these buffers) is needed for every simultaneously active TCP connection, where “active” means sending & receiving data.

If a connection is used bidirectional for sending & receiving data at the same time, enough buffers should be added to be able to support the full TxWindowsSize and RxWindowSize at the same time.

**Note**

The configuration mentioned above is not necessary if not all of your connections are using their maximum WindowSize all the time to reach the best speed possible.

The TCP protocol can freely assign free packet buffers in the system to all socket buffers. Therefore it is not necessary to reserve the maximum number of packet buffers for all sockets that could be used at the same time if you can afford retransmits and their delays of typically ~200ms.

On a shortage, especially when failing to get a buffer for adding received data to a socket buffer (data gets discarded in the TCP layer), the TCP protocol is able to cope with this situation by not ACKing the data and having the peer retransmit it again, giving the application a chance to free some buffers in the meantime.

22.1.3.2 Required buffers

Most of the RAM used by the stack is used for packet buffers. Packet buffers are used to hold incoming and outgoing packets and data in receive and transmit windows of TCP connections.

**Example configuration - Extremely small (4 kBytes)**

This configuration is the smallest available or at least very close. It is intended to be used on MCUs with very little RAM and can be used for applications which are designed for a very low amount of traffic.

```c
#define  ALLOC_SIZE 0x1000  // 4 kBytes RAM
mtu =  576;          // 576 is minimum acc.  // to RFC, 1500 is max. for Ethernet
IP_SetMTU(0, mtu);  // Maximum Transmission Unit is 1500
```
### Example configuration - Small (12 kBytes)

This configuration is a small configuration intended to be used on MCUs with little RAM and can be used for applications which are designed for a medium amount of traffic.

```c
#define ALLOC_SIZE 0x3000 // 12 kBytes RAM
mtu = 576; // 576 is minimum acc. to RFC, 1500 is max. for Ethernet
IP_SetMTU(0, mtu); // Maximum Transmission Unit is 1500 for Ethernet by default
IP_AddBuffers(8, 256); // Small buffers.
IP_AddBuffers(4, mtu + 16); // Big buffers. Size should be mtu + 16 byte for Ethernet header
// (2 bytes type, 2*6 bytes MAC, 2 bytes padding)
IP_ConfTCPSpace(2 * (mtu-40), 1 * (mtu-40)); // Define TCP Tx and Rx window size
```

### Example configuration - Normal (24 kBytes)

This configuration is a typical configuration for many MCUs that have a fair amount of internal RAM. It can be used for applications which are designed for a higher amount of traffic and/or multiple client connections.

```c
#define ALLOC_SIZE 0x6000 // 24 kBytes RAM
mtu = 1500; // 576 is minimum acc. to RFC, 1500 is max. for Ethernet
IP_SetMTU(0, mtu); // Maximum Transmission Unit is 1500 for Ethernet by default
IP_AddBuffers(12, 256); // Small buffers.
IP_AddBuffers(6, mtu + 16); // Big buffers. Size should be mtu + 16 byte for Ethernet header
// (2 bytes type, 2*6 bytes MAC, 2 bytes padding)
IP_ConfTCPSpace(3 * (mtu-40), 2 * (mtu-40)); // Define TCP Tx and Rx window size
```

### Example configuration - Large (128 kBytes)

This configuration is a large configuration intended to be used on MCUs with many external RAM. It can be used for applications which are designed for a high amount of traffic and multiple client/server connections at the same time.

```c
#define ALLOC_SIZE 0x20000 // 128 kBytes RAM
mtu = 1500; // 576 is minimum acc. to RFC, 1500 is max. for Ethernet
IP_SetMTU(0, mtu); // Maximum Transmission Unit is 1500 for Ethernet by default
IP_AddBuffers(50, 256); // Small buffers.
IP_AddBuffers(50, mtu + 16); // Big buffers. Size should be mtu + 16 byte for Ethernet header
// (2 bytes type, 2*6 bytes MAC, 2 bytes padding)
IP_ConfTCPSpace(8 * (mtu-40), 8 * (mtu-40)); // Define TCP Tx and Rx window size
```

**Note**

Do not configure “1 * (mtu-40)” (only one one packet) for the TxWindowSzize if TCP delayed ACKs are enabled (default). This might lead to a delay of ~200ms before the peer ACKs the sent data as it will wait for its retransmit delay time (default ~200ms) for at least a second packet to arrive.
If you intend to run a super small configuration with only one packet for the TxWindowSize, please disable delayed ACK support in the stack by configuring the define IP_SUPPORT_TCP_DELAYED_ACK to 0.
### 22.2 Compile-time configuration

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

#### 22.2.1 Compile-time configuration switches

22.2.2 Debug level

embOS/IP can be configured to display debug information at higher debug levels to locate a problem (Error) or potential problem. To display information, embOS/IP uses the logging routines (see chapter Debugging on page 845). These routines can be blank, they are not required for the functionality of embOS/IP. In a target system, they are typically not required in a release (production) build, since a production build typically uses a lower debug level.

If \((\text{IP\_DEBUG} = 0)\): used for release builds. Includes no debug options.

If \((\text{IP\_DEBUG} = 1)\): \text{IP\_PANIC()} is mapped to \text{IP\_Panic()}.  

If \((\text{IP\_DEBUG} \geq 2)\): \text{IP\_PANIC()} is mapped to \text{IP\_Panic()} and logging support is activated.
The embOS/IP implementation of the Internet Protocol version 6 (IPv6) allows you a fast and easy transition from IPv4 only applications to dual IPv4 and IPv6 applications.
### 23.1 embOS/IP IPv6

The embOS/IP IPv6 add-on is an optional extension which can be seamlessly integrated into your TCP/IP application. It combines a maximum of performance with a small memory footprint.

The following table shows the contents of the embOS/IP IPv6 add-on root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>

23.2 Feature list

- Low memory footprint
- Easy to implement
- Internet Protocol version 6 (IPv6)
- Internet Control Message Protocol (ICMPv6)
- Neighbor Discovery Protocol (NDP)
- Multicast Listener Discovery (MLD)
- Stateless Address autoconfiguration (SLAAC)
- Standard socket interface
- No configuration required
23.3 IPv6 backgrounds

IPv6 is a network layer protocol. It is the most recent version of the Internet Protocol and is intended to replace IPv4 in the near future. The name IPv6 is commonly used generic term for an Internet protocol suite and summarizes the following protocols:

- Internet Protocol version 6 (IPv6)
- Internet Control Message Protocol (ICMPv6)
- Neighbor Discovery Protocol (NDP)
- Multicast Listener Discovery (MLD)

The IPv6 has a larger address space, supports stateless address autoconfiguration and makes extensive use of multicasting. The IPv6 protocol header is designed to simplify processing by routers and is extensible for new requirements.

---

### Internet Protocol header comparison

- **Application layer**: DHCPv6, DNSv6, HTTP, FTP, ...
- **Transport layer**: TCP, UDP
- **Network layer**: IPv6, ICMPv6 (MLD, NDP)
- **Link layer**: Ethernet (IEEE 802.3), ...

---

The IPv6 header has a fixed length of 40 bytes and does not include any option. Contrary to IPv4, options are stored in extension headers. The benefit of this separation is that a router never needs to parse the header so that the processing is more efficient although the header size is at least twice the size of an IPv4 header.

The most conspicuous difference between IPv4 and IPv6 is the length of the address. The length of an IPv6 address is 128 bits, compared to 32 bits in IPv4. The address space therefore has $2^{128}$ addresses. Today public IPv4 addresses have become relatively scarce. This problem can be solved by using IPv6.

**Internet Protocol header comparison**

The IPv6 header contains the Internet Protocol version, traffic classification options the length of the payload, the optional extension or payload which follows the header, a hop limit and the source and destination addresses.
Compared to the IPv4 header, the number of header elements is simplified. Unnecessary or ambiguous elements such as header checksum or IHL removed. Other elements like Time to live, which is in practice used as hop limit, are renamed.

### 23.3.1 IPv6 address types

There are three types of IPv6 addresses:

- Unicast
- Multicast
- Anycast

IPv6 addresses are represented as eight groups of four hexadecimal digits separated by colons.

For example: \texttt{fe80:0000:0000:0000:0222:c7ff:feff:ff23} is a link local unicast address.

IPv6 addresses may be abbreviated to shorter notations. The following rules for abbreviation are defined by RFC 5952 "A Recommendation for IPv6 Address Text Representation”.

- One or more leading zeros from any groups of hexadecimal digits are removed; this is usually done to either all or none of the leading zeros. For example, the group 0222 is converted to 222.
- Consecutive sections of zeros are replaced with a double colon (\texttt{::}). The double colon can only be used once in an address, as multiple use would render the address indeterminate.

Using the recommended rules for abbreviation the textual representation of the example IPv6 address can be simplified to \texttt{fe80::222:c7ff:feff:ff23}.

#### 23.3.1.1 Link-local unicast addresses

An IPv6 link-local unicast address is always automatically configured for each interface. It is required for Neighbor Discovery and DHCPv6 processes. A link-local address is also useful in single-link networks with no router. It can be used to communicate between hosts on a single-link. IPv6 link-local addresses will never be forwarded by an IPv6 router.
The first 64 bits are link-local address prefix. Prefixes for IPv6 subnets are expressed in the same way as Classless Inter-Domain Routing (CIDR) notation for IPv4. An IPv6 prefix is written in address/prefix-length notation. The prefix for link-local addresses is always \texttt{fe80::/64}.

The second 64 bits are the interface identifier. The interface identifier is a modified EUI-64 identifier. Please refer to the appendix of RFC 4291 "IP Version 6 Addressing Architecture" for further information.

### 23.3.1.2 Global unicast addresses

IPv6 global unicast addresses are the counterpart to IPv4 public addresses. They are globally routable and reachable on the IPv6 Internet.

RFC 3587 defines global addresses that are currently being used on the IPv6 Internet. According to RFC 3587 an IPv6 global unicast address consists of of four parts:

- **Fixed high-order bits** - 3 bits: 001
- **Global routing prefix** - 45 bits: Together with the three high-order bits builds the global routing prefix the site prefix. A site is an autonomously operating network that is connected to the IPv6 Internet. A site prefix identifies an individual site of an organization, so that routers can forward IPv6 traffic matching the 48-bit prefix to the routers of the organization’s site.
- **Subnet ID** - 16 bits: Used to identify subnets within an organization’s site.
- **Interface ID** - 64 bits: Normally, the interface identifier is a modified EUI-64 identifier.

### 23.3.2 Further reading for IPv6

This chapter explains the usage of the embOS/IP IPv6 add-on. It describes all functions which are required to build a network application using IPv6. For a deeper understanding about how the protocols of the Internet protocol suite works use the following references.
The following Request for Comments (RFC) define the relevant protocols of the Internet protocol suite and have been used to build the embOS/IP IPv6 add-on. They contain all required technical specifications. The listed books are simpler to read as the RFCs and give a general survey about the interconnection of the different protocols.

### 23.3.2.1 IPv6 Request for Comments (RFC)

### 23.3.2.2 Related books for IPv6

- [Hagen] - IPv6 Essentials, Silvia Hagen  
  ISBN: 978-1449319212  
- [Davies] - Understanding IPv6, Joseph Davies  
  ISBN: 978-0735659148
23.4 Include IPv6 to your embOS/IP start project

Integration of embOS/IP is a relatively simple process, which consists of the following steps:

- Step 1: Open an embOS/IP project and compile it.
- Step 2: Add embOS/IP IPv6 add-on to the start project.
- Step 3: Build the project and test it.

The following steps presume that you use a project with the recommended project structure. If your project structure differs, keep in mind that you potentially have to add additional directories to your include path.

23.4.1 Open an embOS/IP project and compile it

To add the embOS/IP IPv6 add-on to your project, you need a running embOS/IP project. For a step by step tutorial to setup an embOS/IP project refer to Running embOS/IP on target hardware on page 53.

23.4.2 Add the embOS/IP IPv6 add-on to the start project

Add all source files in the following directory to your project:

- IP

The embOS/IP IPv6 add-on default configuration is preconfigured with valid values, which matches the requirements of the most applications.

23.4.2.1 Enable IPv6 support

To enable the IPv6 support, you have to add the following define to your IP_Conf.h:

```
#define IP_SUPPORT_IPV6 1
```

Build the project. It should compile without error and warnings.

To include IPv6 in your application you need to add the IPv6 related protocols by calling IP_IPV6_Add() in the function IP_X_Config() as shown below:

```c
void IP_X_Config(void) {
    int mtu;
    int IFaceId;
    ...
    IFaceId = IP_AddEtherInterface(DRIVER); // Add driver for your hardware.
    ...
    // Add protocols to the stack.
    // IP_TCP_Add();
    // IP_UDP_Add();
    // IP_ICMP_Add();
    #if IP_SUPPORT_IPV6
    // IP_IPV6_Add(IFaceId);
    #endif
}
```

Refer to Configuring embOS/IP on page 525 for more information on IP_X_Config().

The link-local IPv6 address will be generated automatically during initialization. Please ensure that the MAC address of your target is unique in your network segment, since it is used to build the interface identifier part of the IPv6 address.
23.4.2.2 Configure the MTU and the Tx/Rx window sizes

The Maximum Transmission Unit (MTU) is the largest number of payload bytes that can be sent in a packet. A typical value for Ethernet is 1500, since the maximum size of an Ethernet packet is 1518 bytes. Since Ethernet uses 12 bytes for MAC addresses, 2 bytes for type and 4 bytes for CRC, 1500 bytes “payload” remain.

As opposed to IPv4, which requires at least 576 bytes as MTU, RFC2460 defines that IPv6 has to use at least 1280 bytes. If you do not use the Ethernet maximum of 1500 bytes, check in your IP_X_Config() that the MTU size is not smaller as 1280 bytes.

The TCP transmit and receive window sizes, configured with IP_ConfTCPSpace(), should also be checked. An IPv4 header without options is 20 bytes. Together with the TCP header the payload of a normal TCP/IPv4 packet can be up to 1460 bytes.

It is a good approach to calculate the sizes of the transmit window and receive window with the following formula: \( x \times (MTU - (IP \text{ header size} + TCP \text{ header size}) \)

\( x \) is the number of big packets, which are available for each TCP connection.

embOS/IP sample configurations up to embOS/IP version 2.20 always include a call of IP_ConfTCPSpace() and computes a matching window sizes for IPv4 targets with this formula.

Example

```c
IP_ConfTCPSpace(3 * (Mtu - 40), 3 * (Mtu - 40)); // Define TCP Tx and Rx window size
```

Since the IPv6 header is 40 bytes, the payload of a normal TCP/IPv6 packet is limited to a maximum of 1440 bytes (Max. Ethernet MTU - (IPv6 header size + TCP header size), 1500 - (40 + 20)). You need to change the transmit window and receive window sizes to ensure the best possible TCP performance.

Example

```c
IP_ConfTCPSpace(3 * (Mtu - 60), 3 * (Mtu - 60)); // Define TCP Tx and Rx window size
```

23.4.2.3 Enable terminal output for IPv6 messages

In debug builds of embOS/IP, logging messages can be used. IP_SetLogFilter() sets a mask that defines which logging messages should be logged. To output IPv6 related logging messages the message type IP_MTYPE_IPV6 needs to be added.

Example

```c
IP_SetLogFilter(IP_MTYPE_INIT, // Output all messages from init
    IP_MTYPE_LINK_CHANGE, // Output a msg if link status changes
    IP_MTYPE_DHCP, // Output general DHCP status messages
    IP_MTYPE_IPV6); // Output IPv6 status messages
```

23.4.2.4 Select the start application

For testing of your embOS/IP IPv6 add-on integration, start with the code found in the Application folder. Add one of the applications to your project (for example OS_IP_SimpleServer_IPv6.c)

23.4.3 Build the project and test it

Build the project. It should compile without errors and warnings. If you encounter any problem during the build process, check your include path and your project configuration settings. To test the project, download the output into your target and start the application.
A target which uses IPv4 and IPv6 should output similar logging messages as shown below:

```
0:000 MainTask - INIT: Init started.
0:000 MainTask - DRIVER: Found PHY with Id 0x2000 at addr 0x1
0:000 MainTask - INIT: Link is down
0:000 MainTask - INIT: Init completed
0:000 IP_Task - INIT: IP_Task started
3:000 IP_Task - LINK: Link state changed: Full duplex, 100MHz
3:400 IP_Task - NDP: Link-local IPv6 addr.:
   FE80::0000:0000:0000:0222:C7FF:EFFF:FF22 added to IFace: 0
4:000 IP_Task - DHCPc: Sending discover!
5:002 IP_Task - DHCPc: IFace 0: Offer: IP: 192.168.1.12, Mask: 255.255.255.0, GW:
   192.168.1.1.
6:000 IP_Task - DHCPc: IP addr. checked, no conflicts
6:001 IP_Task - DHCPc: Sending Request.
6:001 IP_Task - DHCPc: IFace 0: Using IP: 192.168.1.12, Mask: 255.255.255.0, GW:
   192.168.1.1.
```

ICMPv6 is always activated. This means that you can ping your target. Open the command line interface of your operating system and enter ping <TargetAddress>, to check if the stack runs on your target. The target should answer all pings without any error.

![Ping result](image.png)
23.5 Configuration

The embOS/IP IPv6 add-on can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

23.5.1 IPv6 Compile time configuration

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define U8, which the preprocessor would replace with unsigned char.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

<td>Sets a callback to allow processing of DNS Search List Option.</td>
</tr>
</tbody>
</table>
### 23.6.1 IP_IPV6_Add()

**Description**

Adds IPv6 to the stack and initializes the specified interface.

**Prototype**

```c
void IP_IPV6_Add(unsigned IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Additional information**

The call of `IP_IPV6_Add()` adds and initializes all required IPv6 protocols to the stack. This means that Internet Control Message Protocol version 6 (ICMPv6), Multicast Listener Discovery (MLD) and Neighbor Discovery Protocol (NDP) are added and initialized.

Part of the initialization is the generation of a link-local address, since all IPv6 hosts require such an address. The link-local address is derived from the MAC address of an interface and the link-local prefix FE80::/64. The uniqueness of the address on the subnet is tested using the Duplicate Address Detection (DAD) method.

Note: You need to set the compile time switch `IP_SUPPORT_IPV6` to 1 to enable the stack to work in dual stack mode supporting IPv4 and IPv6.

**Example**

```c
void IP_X_Config(void) {
    int Mtu;

    IP_AssignMemory(&_aDrvPool, sizeof(&_aDrvPool)); // Assigning memory should be the first thing
    IP_AddEtherInterface(&IP_Driver_STM32F207); // Add Ethernet driver for your hardware
    IP_SetHWAddr("\x00\x22\xC7\xFF\xFF\xFF\x22"); // MAC addr: Needs to be unique for production units
    IP_DHCPC_Activate(0, "TARGET", NULL, NULL); // Request an IPv4 address
    // // Run-time configure buffers.
    // The default setup will do for most cases.
    // //
    // Mtu = 1500;
    // 576 is minimum for IPv4,
    // 1280 is minimum for IPv6,
    // 1500 is max. for Ethernet
    IP_SetMTU(0, Mtu);
    IP_AddBuffers(12, 256); // Small buffers.
    IP_AddBuffers(6, Mtu + 16); // Big buffers.
    IP_ConfTCPSpace(3 * (Mtu - 60), 3 * (Mtu - 60)); // Define TCP Tx and Rx window size
    // // Define log and warn filter
    //
    IP_SetWarnFilter(0xFFFFFFFF); // 0xFFFFFFFF: Do not filter:
    IP_SetLogFilter(IP_MTYPE_INIT | IP_MTYPE_LINK_CHANGE | IP_MTYPE_DHCP | IP_MTYPE_IPV6);
    // // Add protocols to the stack
    //
    IP_UDP_Add(); // Add transport protocol: UDP.
    IP_TCP_Add(); // Add transport protocol: TCP.
    IP_ICMP_Add(); // Add ICMPv4.
    IP_IPV6_Add(0); // Add IPv6, includes ICMPv6, MLD and NDP on interface 0.
}
```
})
23.6.2 IP_IPV6_AddUnicastAddr()

**Description**

Adds an additional IPv6 unicast address to the interface.

**Prototype**

```c
int IP_IPV6_AddUnicastAddr(       unsigned    IFaceId ,
                           const  U8       *  pAddr );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pAddr</td>
<td>Pointer to the 16 byte IPv6 address which should be added to the network interface.</td>
</tr>
</tbody>
</table>

**Return value**

- 0  OK. IPv6 address added to the network interface.
- 1  Error. IPv6 address could not be added to the network interface.

**Additional information**

Normally, a link-local address (prefix FE80::/64) derived from the MAC address of the interface has been set during initialization of the stack.
23.6.3 IP_IPV6_ChangeDefaultConfig()

Description
Changes the default IPv6 configuration of the stack.

Prototype

```
void IP_IPV6_ChangeDefaultConfig(unsigned IFaceId,
                                  unsigned Option,
                                  unsigned OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option</td>
<td>Option to enable/disable.</td>
</tr>
</tbody>
</table>
| OnOff     | • 1: Enable option  
            • 0: Disable option |

Additional information

In most situations, the default configuration of the stack needs no changes. To adapt the behavior of the stack for the needs of some special use cases, the default behavior can be changed.

Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_GENERATE_LINK_LOCAL_ADDR</td>
<td>Generate a link-local address fe80::/64</td>
</tr>
<tr>
<td>IPV6_ICMPV6_MLD_ADD_DEF_ADDR</td>
<td>Add multicast addresses ALL-Nodes and All-Router to the interface.</td>
</tr>
<tr>
<td>IPV6_USE_SLAAC</td>
<td>Use Stateless Address Autoconfiguration (SLAAC).</td>
</tr>
<tr>
<td>IPV6_USE_ROUTER_ADVERTISEMENTS</td>
<td>Use configuration options supplied through Router Advertisements.</td>
</tr>
</tbody>
</table>
23.6.4  IP_IPV6_GetIPv6Addr()

Description
Returns an IPv6 address and optionally the number of configured IPv6 address of the selected interface.

Prototype

```c
void IP_IPV6_GetIPv6Addr(unsigned IFaceId, U8 AddrId, IPV6_ADDR * pIPv6Addr, U8 * pNumAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface identifier.</td>
</tr>
<tr>
<td>AddrId</td>
<td>Address index.</td>
</tr>
<tr>
<td>pIPv6Addr</td>
<td>IPv6 address for the result (Could be NULL).</td>
</tr>
<tr>
<td>pNumAddr</td>
<td>Number of configured IPv6 addresses (Could be NULL).</td>
</tr>
</tbody>
</table>
23.6.5 IP_IPV6_ParseIPv6Addr()

**Description**
Transfroms an IPv6 address separated by colons into a byte stream (big endian byte order).

**Prototype**

```c
int IP_IPV6_ParseIPv6Addr(const char * sHost,
                         IPV6_ADDR * pIPv6Addr);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sHost</td>
<td>Pointer to the IPv6 address string to parse.</td>
</tr>
<tr>
<td>pIPv6Addr</td>
<td>Pointer to an IPv6 address structure to store the converted byte stream.</td>
</tr>
</tbody>
</table>

**Return value**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK.</td>
</tr>
<tr>
<td>-1</td>
<td>Error. Not every character in address are hexa values (0-f) or colons (:).</td>
</tr>
<tr>
<td>-2</td>
<td>Error. Too much characters for 16bit block.</td>
</tr>
<tr>
<td>-3</td>
<td>Error. Illegal number of colons in a row (“:::“)</td>
</tr>
<tr>
<td>-4</td>
<td>Error. “::” is used twice.</td>
</tr>
<tr>
<td>-5</td>
<td>Error. Address string to long.</td>
</tr>
<tr>
<td>-6</td>
<td>Error. Too much colons.</td>
</tr>
<tr>
<td>-7</td>
<td>Error. Parameter invalid</td>
</tr>
</tbody>
</table>

**Additional information**

IPv6 addresses are represented in eight 16-bit blocks. Each 16-bit block is converted to a 4-digit hexadecimal number and separated by colons. For example: 2001:0db8:0000:0000:0001:0000:0234:0001.

The representation can be simplified by suppressing the leading zeros within each 16-bit block. For example: 2001:db8:0:0:1:0:234:1.

IPv6 addresses that contain long sequences of zeros can be further simplified. A single contiguous sequence of 16-bit blocks set to 0 in the colon hexadecimal format can be compressed to ”::“. For example: 2001:db8::1:0:234:1.

**Example**

```c
static void _ParseAndPrintIPv6Addr (void) {
    IPV6_ADDR IPv6Addr;
    IP_IPV6_ParseIPv6Addr(&IPv6Addr, "2001:db8::1:0:234:1");
    IP_Logf_Application("IPv6 addr.: %n", IPv6Addr.Union.aU8);
}
```

**Output:**

```
IPv6 addr.: 2001:0DB8:0000:0000:0001:0000:0234:0001
```
23.6.6  IP_IPV6_SetDefHopLimit()

Description
Adds a default hop limit to the interface.

Prototype

```c
int IP_IPV6_SetDefHopLimit(unsigned IFaceId,
                      U8     HopLimit);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>HopLimit</td>
<td>Hop limit that should be used as default.</td>
</tr>
</tbody>
</table>

Return value

- 0  Ok. Hop limit set.
- 1  Error.
23.6.7   IP_IPV6_SetGateway()

Description
Sets the gateway server address of the selected interface.

Prototype

```c
int IP_IPV6_SetGateway(       unsigned    IFaceId ,
                             const  char      *  sIFaceAddr ,
                             const  char      *  sRouterAddr );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Interface identifier</td>
</tr>
<tr>
<td>sRouterAddr</td>
<td>IPv6 address string. For example “2001:4860:4860::8888”</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt; 0</td>
<td>Error. Gateway address format invalid.</td>
</tr>
<tr>
<td>= 0</td>
<td>Could not add gateway. - IPv6 not enabled on the selected interface or gateway is already in list or required memory could not allocated.</td>
</tr>
<tr>
<td>= 1</td>
<td>Gateway added.</td>
</tr>
</tbody>
</table>
23.6.8 IP_IPV6_SetLinkLocalUnicastAddr()

Description
Adds a link local unicast address to the interface.

Prototype

```c
void IP_IPV6_SetLinkLocalUnicastAddr(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface identifier.</td>
</tr>
</tbody>
</table>
23.6.9  IP_IPV6_INFO_GetConnectionInfo()

Description
Retrieves the connection information for a connection handle. The connection handle is typically obtained via a call to IP_INFO_GetConnectionList().

Prototype
int IP_IPV6_INFO_GetConnectionInfo ( IP_CONNECTION_HANDLE   hConn,
                                         IP_IPV6_CONNECTION * pConInfo);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>h</td>
<td>Connection handle.</td>
</tr>
<tr>
<td>pConInfo</td>
<td>Pointer on an IP_CONNECTION structure that will be filled.</td>
</tr>
</tbody>
</table>

Return value

0        OK, Information retrieved
1        Error, typically because the connection pointer is no longer in list
23.6.10 IP_ICMPV6_MLD_AddMulticastAddr()

Description
Adds an additional multicast address to the given interface.

Prototype

```c
int IP_ICMPV6_MLD_AddMulticastAddr(unsigned IFaceId, IPV6_ADDR * pMultiCAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pMultiCAddr</td>
<td>Pointer to the 16 byte IPv6 multicast address which should be added to the network interface.</td>
</tr>
</tbody>
</table>

Return value

1 OK. IPv6 multicast address added to the network interface.
0 Error. IPv6 multicast address could not be added to the network interface.

Additional information

The IPv6 multicast addresses All-Routers (FF01:0:0:0:0:0:0:2) and All-Nodes (FF01:0:0:0:0:0:0:1) are always automatically added to the network interface, since they are required for correct functioning of the IPv6 implementation.
23.6.11  IP_ICMPV6_MLD_RemoveMulticastAddr()

Description
Removes a multicast address from the given interface.

Prototype

```c
int IP_ICMPV6_MLD_RemoveMulticastAddr(unsigned IFaceId, IPV6_ADDR * pIPv6Addr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pIPv6Addr</td>
<td>Pointer to the 16 byte IPv6 multicast address which should be removed.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>OK. IPv6 multicast address removed from the network interface.</td>
</tr>
<tr>
<td>0</td>
<td>Error. IPv6 multicast address could not be removed.</td>
</tr>
</tbody>
</table>
23.6.12  IP_ICMPV6_NDP_SetDNSSLCallback()

Description
Sets a callback to allow processing of DNS Search List Option. (For further information to
the DNS Search List Option refer to [6], section 5.2.

Prototype

```c
void IP_ICMPV6_NDP_SetDNSSLCallback
    (unsigned IFaceId,
     void      (  * pfHandleDNSSLOpt)
    (unsigned IFaceId , U8 * pData , unsigned NumBytes , U32 Lifetime ));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pfHandleDNSSLOpt</td>
<td>Callback with more information.</td>
</tr>
</tbody>
</table>
23.7 IPv6 Socket API extensions

The socket interface was developed for Unix in the early 1980s and has also been implemented on a wide variety of non-Unix systems. Today it is the de facto standard Application Program Interface (API) for TCP/IP applications. With the new version of the Internet protocol some changes were required to support IPv6. RFC 3493 "Basic Socket Interface Extensions for IPv6" describes the recommended extensions to the socket API.

In the current version of the embOS/IP IPv6 add-on are the following extensions included.

### Structures

<table>
<thead>
<tr>
<th>Structures</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sockaddr_in6</td>
<td>Structure to handle IPv6 addresses.</td>
</tr>
</tbody>
</table>

### Socket options

<table>
<thead>
<tr>
<th>Socket options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPV6_JOIN_GROUP</td>
<td>Join an IPv6 multicast group on a specified local interface.</td>
</tr>
<tr>
<td>IPV6_LEAVE_GROUP</td>
<td>Leave an IPv6 multicast group on a specified local interface.</td>
</tr>
</tbody>
</table>

23.7.1 Structure sockaddr_in6

**Description**

Structure to handle IPv6 addresses.

**Prototype**

```c
typedef struct sockaddr_in6 {
    U16 sin6_family;
    U16 sin6_port;
    U32 sin6_flowinfo;
    IPV6_ADDR sin6_addr;
    U32 sin6_scope_id;
} SOCKADDR_IN6;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sin6_family</td>
<td>Protocol family (AF_INET6).</td>
</tr>
<tr>
<td>sin6_port</td>
<td>Transport layer port stored in network byte order.</td>
</tr>
<tr>
<td>sin6_flowinfo</td>
<td>Flow information.</td>
</tr>
<tr>
<td>sin6_addr</td>
<td>16-bytes IPv6 address.</td>
</tr>
<tr>
<td>sin6_scope_id</td>
<td>Set of interfaces for a scope.</td>
</tr>
</tbody>
</table>

This structure is required to pass IPv6 addresses to socket interface functions like `accept()`, `bind()`, `connect()`, `recvfrom()` and `sendto()`. For further information about usage, please refer to Porting an IPv4 application to IPv6 on page 563 and IPv6 API functions on page 548 for details about the usage of the socket API functions.
23.8  Porting an IPv4 application to IPv6

TCP/IP applications written using the socket API have in the past enjoyed a high degree of portability. This portability was kept in mind while the socket API was extended to support IPv6. Complete compatibility for existing IPv4 applications is always ensured.

Besides smaller enhancements like some new socket options, a new socket address structure has been added to carry IPv6 addresses.

The following sections demonstrate, using the supplied IPv4 example applications, which parts have to be changed to communicate via IPv6. All examples are also part of the embOS/IP IPv6 add-on shipment.

23.8.1  Porting an IPv4 server application to IPv6

The main difference between an IPv4 and an IPv6 socket application lay in the functions which pass a socket address structure as a parameter. The relevant functions are `accept()`, `bind()`, `connect()`, `recvfrom()` and `sendto()`.

The prototype of the `sockaddr_in6` structure is shown below.

```c
typedef struct sockaddr_in6 {
    U16   sin6_family;    // AF_INET6
    U16   sin6_port;      // Transport layer port stored in network byte order.
    U32   sin6_flowinfo;  // IPv6 flow information
    IPV6_ADDR sin6_addr;  // IPv6 address
    U32   sin6_scope_id;  // Set of interfaces for a scope
} SOCKADDR_IN6;
```

The `sockaddr_in6` structure is 28 bytes. For further information, please refer to `Structure sockaddr_in6` on page 562. embOS/IP IPv6 add-on comes with three version of `OS_IP_SimpleServer`.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OS_IP_SimpleServer.c</td>
<td>IPv4 version of the simple TCP server example. Server listens on port 23 for IPv4 clients.</td>
</tr>
<tr>
<td>OS_IP_SimpleServer_IPv6.c</td>
<td>IPv6 version of the simple TCP server example. Server listens on port 23 for IPv6 clients.</td>
</tr>
</tbody>
</table>
23.8.1.1 TCP/IPv4 server sample code

Listen to a port

The supplied example OS_IP_SimpleServer.c is a simple Telnet server listening on port 23 that outputs the current system time for each character received. It uses bind() to assign a socket address to a socket and accept() to create a new connected socket. To assign a socket address to a socket a sockaddr structure needs to be initialized and used as parameter for bind().

The following excerpt of IP_OS_SimpleServer.c shows a code snippet, which creates an IPv4 socket, binds it to TCP port 23 and sets it into listening state.

```c
/*********************************************************************
*                          _ListenAtTcpAddr()                          *
* Function description                                                                                           *
* Creates a socket for port 23 and sets it into listening state.                                               *
* The only step left is to call accept() to actually wait for a client to connect.                             *
* Return value                                                                                                  *
* O.K. : Socket handle.                                                                                         *
* Error: SOCKET_ERROR.                                                                                          */
static int _ListenAtTcpAddr ( void ) {
    struct sockaddr_in Addr;
    int hSock;
    int r;

    hSock = socket(AF_INET, SOCK_STREAM, 0);
    if (hSock != SOCKET_ERROR) {
        IP_MEMSET(&Addr, 0, sizeof(Addr));
        Addr.sin_family = AF_INET;
        Addr.sin_port = htons(23);
        Addr.sin_addr.s_addr = INADDR_ANY;
        r = bind(hSock, (struct sockaddr *)&Addr, sizeof(Addr));
        if (r != 0) {
            hSock = SOCKET_ERROR;
        } else {
            r = listen(hSock, 1);
            if (r != 0) {
                hSock = SOCKET_ERROR;
            }
        }
    }
    return hSock;
}
```

The socket creation is done with the following line of code:

```c
hSock = socket(AF_INET, SOCK_STREAM, 0);
```

AF_INET is the address family for IPv4. The rest of the code snippet fills the sockaddr_in structure and pass it, together with the size of the sockaddr_in structure, to bind().

The IPv4 socket address structures sockaddr_in and sockaddr have a size of 16 bytes. For further information about the sockaddr_in structure, please refer to the Structure sockaddr_in on page 295.

Accept connection

The following excerpt of IP_OS_SimpleServer.c shows a code snippet, which accepts connections using the socket returned by the call of _ListenAtTcpAddr().

```c
/*********************************************************************
*                          _TelnetTask()                           *
*/
```
Function description

Creates a parent socket and handles clients that connect to the server. This sample can handle one client at the same time. Each client that connects creates a child socket that is then passed to the process routine to detach client handling from the server functionality.

```
static void _TelnetTask(void) {
    struct sockaddr Addr;
    int AddrLen;
    int hSockParent;
    int hSockChild;

    AddrLen = sizeof(Addr);
    while (1) {
        // Try until we get a valid parent socket.
        hSockParent = _ListenAtTcpAddr();
        if (hSockParent == SOCKET_ERROR) {
            OS_Delay(5000);
            continue; // Error, try again.
        }
        while (1) {
            // Try until we get a valid child socket.
            // Typically accept() will only return when a valid client has connected.
            hSockChild = accept(hSockParent, &Addr, &AddrLen);
            if (hSockChild == SOCKET_ERROR) {
                continue; // Error, try again.
            }
            IP_Logf_Application("New client (%i) accepted.", Addr.sin_addr.s_addr);
            _Process(hSockChild); // Process the client.
            closesocket(hSockChild); // Close connection to client from our side (too).
        }
    }
}
```

The `accept()` function returns a new connected socket which is used to transfer data between the embOS/IP host and the client. The optional output parameters `pAddr` and `pAddrlen` of `accept()` are still only used for debugging purposes. We output the IPv4 address of the client after connecting to our host. The output should be similar to the following:

Telnet - New client (192.168.11.29) accepted.

The new connected socket is passed to the function `_Process()` which handles the data transmission. When the process returns, the socket will be closed and the host can process further client requests.

For further information about `accept()`, please refer to `accept` on page 258.

### 23.8.1.2 Required changes to port the TCP/IPv4 server sample code to TCP/IPv6

To port these simple telnet style server to IPv6, `_ListenAtTcpAddr()` and `_TelnetTask()` has to be modified. The rest of the example `IP_OS_SIMPLESERVER.c` keeps untouched.

#### Listen to a port

 `_ListenAtTcpAddr()` needs to create an IPv6 socket instead of an IPv4 socket and the `sockaddr_in` structure has to be replaced by a `sockaddr_in6` structure.

The socket creation changes from:

```
hSock = socket(AF_INET, SOCK_STREAM, 0);
```

to:

```
hSock = socket(AF_INET6, SOCK_STREAM, 0);
```
hSock = socket(AF_INET6, SOCK_STREAM, 0);

AF_INET6 is the address family for IPv6.

The modified function _ListenAtTcpAddr() looks like the code snippet below.

```c
/***************************************************************************/
/*
*    _ListenAtTcpAddr()
* 
* Function description
*   Creates a socket for port SERVER_PORT and sets it into listening
* state. The only step left is to call accept() to actually wait for
* a client to connect.
* 
* Return value
*   O.K. : Socket handle.
*   Error: SOCKET_ERROR .
*/
static int _ListenAtTcpAddr(void) {
    struct sockaddr_in6 Addr;
    int hSock;
    int r;

    hSock = socket(AF_INET6, SOCK_STREAM, 0);
    if (hSock != SOCKET_ERROR) {
        Addr.sin6_family = AF_INET6;
        Addr.sin6_port = htons(23);
        Addr.sin6_flowinfo = 0;
        IP_MEMSET(&Addr.sin6_addr.Union.aU8[0], 0, IPV6_ADDR_LEN);
        Addr.sin6_scope_id = 0;
        r = bind(hSock, (struct sockaddr *)&Addr, sizeof(Addr));
        if (r != 0) {
            hSock = SOCKET_ERROR;
        } else {
            r = listen(hSock, 1);
            if (r != 0) {
                hSock = SOCKET_ERROR;
            }
        }
    }
    return hSock;
}
```

Compared to the IPv4 version of these function, AF_INET6 is used to specify the address family to create an IPv6 socket. The port number is still 23 and the address element sin6_addr is set to zero, which means that the socket will be bound to all available interfaces. The new elements, sin6_flowinfo and sin6_scope, are set to zero.

Accept connection

The function _TelnetTask() is nearly untouched. The only change is the sockaddr_in6 structure instead of the sockaddr structure used in the IPv4 code.

```c
/***************************************************************************/
/*
*    _TelnetTask()
* 
* Function description
*   Creates a parent socket and handles clients that connect to the
* server. This sample can handle one client at the same time. Each
* client that connects creates a child socket that is then passed
* to the process routine to detach client handling from the server
* functionality.
*/
static void _TelnetTask(void) {
    struct sockaddr_in6 Addr;
    int AddrLen;
    int hSockParent;
    int hSockChild;

    AddrLen = sizeof(Addr);
```
while (1) {
    //
    // Try until we get a valid parent socket.
    //
    hSockParent = _ListenAtTcpAddr();
    if (hSockParent == SOCKET_ERROR) {
        OS_Delay(5000);
        continue; // Error, try again.
    }
}

while (1) {
    //
    // Try until we get a valid child socket.
    // Typically accept() will only return when
    // a valid client has connected.
    //
    hSockChild = accept(hSockParent, (struct sockaddr *)&Addr, &AddrLen);
    if (hSockChild == SOCKET_ERROR) {
        continue; // Error, try again.
    }
    IP_Logf_Application("New client (%n) accepted.", Addr.sin6_addr.Union.aU8);
    _Process(hSockChild); // Process the client.
    closesocket(hSockChild); // Close connection to client from our side (too).
}

The optional output parameters pAddr and pAddrlen of accept() are still only used for debugging purposes. We output the IPv6 address of the client after connecting to our host. The output should be similar to the following:

Telnet - New client (FE80:0000:0000:0000:76D4:35FF:FE8B:5BE5) accepted.

The supplied example OS_IP_SimpleServer_IPv6.c includes all the mentioned changes. You should start with this example to comprehend the code changes.

### 23.8.1.3 Dual stack TCP server sample code

The embOS/IP IPv6 add-on provides IPv4 and IPv6 protocol stacks in the same network node. This means that embOS/IP together with the IPv6 add-on is the ideal starting point to implement applications which can facilitate native communications between nodes using either IPv4 or IPv6 or both.

In the transition phase from IPv4 to IPv6 most server applications need to accept connections from IPv4 clients and from IPv6 clients. The supplied example application OS_IP_SimpleServer_IPv4_IPv6.c demonstrates a possible way to implement such a TCP server application.

The supplied example OS_IP_SimpleServer_IPv4_IPv6.c is a simple Telnet server listening on port 23 that outputs the current system time for each character received.

The following excerpt of IP_OS_SimpleServer_IPv4_IPv6.c shows a code snippet, which creates an IPv4 socket and an IPv6 socket, binds both to TCP port 23 and sets both into listening state. To enhance readability of the example code socket creation and binding are implemented as functions.

```c
/*********************************************************************
*       _ListenAtTcpPort()                                           *
* Function description
* Creates a socket, binds it to a port and sets the socket into     *
* listening state.                                                 *
* Parameter
*  IPProtVer - Protocol family which should be used (PF_INET or PF_INET6). *
*  Port     - Port which should be to wait for connections.          *
* Return value
*  O.K. : Socket handle.                                           *
*  Error: SOCKET_ERROR.                                           *
*********************************************************************/
```
PORTING AN IPv4 APPLICATION TO IPV6

/*
static int _ListenAtTcpPort(unsigned IPProtVer, u16 Port) {
  int hSock;
  int r;

  // Create socket
  hSock = _CreateSocket(IPProtVer);
  if (hSock != SOCKET_ERROR) {
    // Bind it to the port
    r = _BindAtTcpPort(IPProtVer, hSock, Port);
    // Start listening on the socket.
    if (r != 0) {
      hSock = SOCKET_ERROR;
    } else {
      r = listen(hSock, 1);
      if (r != 0) {
        hSock = SOCKET_ERROR;
      }
    }
  }
  return hSock;
}
*/

The function used to create either an IPv4 or an IPv6 socket is listed below:

/*********************************************************************
*       _CreateSocket()
*
* Function description
*   Creates a socket for the requested protocol family.
*
* Parameter
*   IPProtVer - Protocol family which should be used (PF_INET or PF_INET6).
*
* Return value
*   O.K. : Socket handle.
*   Error: SOCKET_ERROR .
*/
static int _CreateSocket(unsigned IPProtVer) {
  int hSock;

  hSock = SOCKET_ERROR;
  // Create IPv6 socket
  if (IPProtVer == PF_INET6) {
    hSock = socket(AF_INET6, SOCK_STREAM, 0);
  }
  // Create IPv4 socket
  if (IPProtVer == PF_INET) {
    hSock = socket(AF_INET, SOCK_STREAM, 0);
  }
  return hSock;
}

The function used to bind either an IPv4 or an IPv6 socket is listed below:

/*********************************************************************
*       _BindAtTcpPort()
*
* Function description
*   Binds a socket to a port.
*
* Parameter
*/
* `IPProtVer` - Protocol family which should be used (PF_INET or PF_INET6).
* `hSock` - Socket handle
* `Port` - Port which should be to wait for connections.

* Return value
* O.K. : Socket handle.
* Error: SOCKET_ERROR.

```c
static int _BindAtTcpPort(unsigned IPProtVer, int hSock, U16 LPort) {
    int r;
    // // Bind it to the port //
    if (IPProtVer == PF_INET6) {
        struct sockaddr_in6 Addr;
        IP_MEMSET(&Addr, 0, sizeof(Addr));
        Addr.sin6_family = AF_INET6;
        Addr.sin6_port = htons(LPort);
        Addr.sin6_flowinfo = 0;
        IP_MEMSET(&Addr.sin6_addr, 0, 16);
        Addr.sin6_scope_id = 0;
        r = bind(hSock, (struct sockaddr *)&Addr, sizeof(Addr));
    }
    if (IPProtVer == PF_INET) {
        struct sockaddr_in Addr;
        IP_MEMSET(&Addr, 0, sizeof(Addr));
        Addr.sin_family = AF_INET;
        Addr.sin_port = htons(LPort);
        Addr.sin_addr.s_addr = INADDR_ANY;
        r = bind(hSock, (struct sockaddr *)&Addr, sizeof(Addr));
    }
    return r;
}
```

To handle client requests on both sockets within one task `select()` is used. For further information to `select()`, please refer to `select` on page 275.

To accept connections on both sockets the listening IPv4 socket and the listening IPv6 socket are added to the read set. `select()` returns if data is available on one of these sockets and `accept()` is called to handle the new connection.

```c
// Try until we get a valid IPv4 parent socket and a valid IPv6 parent socket. //
while (1) {
    hSockParent4 = _ListenAtTcpPort(PF_INET, SERVER_PORT);
    if (hSockParent4 == SOCKET_ERROR) {
        OS_Delay(2000);
        continue; // Error, try again.
    }
    break;
}
while (1) {
    hSockParent6 = _ListenAtTcpPort(PF_INET6, SERVER_PORT);
    if (hSockParent6 == SOCKET_ERROR) {
```
closesocket(hSockParent4);
OS_Delay(2000);
continue; // Error, try again.
} break;
}
// Wait for a connection on one of the both sockets and process the data
// requests after accepting the connection.
while (1) {
    IP_FD_ZERO(&ReadFds); // Clear the set
    IP_FD_SET(hSockParent4, &ReadFds); // Add IPv4 socket to the set
    IP_FD_SET(hSockParent6, &ReadFds); // Add IPv6 socket to the set
    r = select(&ReadFds, NULL, NULL, 5000); // Check for activity. Wait 5 seconds
    if (r <= 0) {
        continue;
    }
    // Check if the IPv4 socket is ready
    if (IP_FD_ISSET(hSockParent4, &ReadFds)) {
        hSockChild = accept(hSockParent4, NULL, NULL);
        if (hSockChild == SOCKET_ERROR) {
            continue; // Error, try again.
        }
        IP_Logf_Application("New IPv4 client accepted.");
    }
    // Check if the IPv6 socket is ready
    else if (IP_FD_ISSET(hSockParent6, &ReadFds)) {
        hSockChild = accept(hSockParent6, NULL, NULL);
        if (hSockChild == SOCKET_ERROR) {
            continue; // Error, try again.
        }
        IP_Logf_Application("New IPv6 client accepted.");
    }
    _Process(hSockChild); // Process the client.
closesocket(hSockChild); // Close connection to client from our side (too).
}

The supplied example OS_IP_SimpleServer_IPv4_IPv6.c is a good starting point to test the reachability of your embedded host via IPv4 and IPv6.
23.9 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the IPv6 modules presented in the tables below have been measured on a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

23.9.1 IPv6 ROM usage

The resource usage of the IPv6 add-on has been measured on a Cortex-M3 system size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP IPv6</td>
<td>approximately 8.0 kBytes</td>
</tr>
</tbody>
</table>

The stated ROM usage is only the additional space that is required to add IPv6 to the embOS/IP IPv4 stack. The total ROM usage for embOS/IP running IPv4 and IPv6 is approximately 28 kBytes.

23.9.2 RAM usage

The total memory requirements of the IPv6 add-on can basically be computed as the sum of the following components:

<table>
<thead>
<tr>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPv6 add-on</td>
<td>approximately 200 bytes</td>
</tr>
<tr>
<td>Unicast address</td>
<td>n * approximately 48 bytes</td>
</tr>
<tr>
<td>Multicast address</td>
<td>n * approximately 28 bytes</td>
</tr>
<tr>
<td>NDP entry</td>
<td>n * 52 bytes</td>
</tr>
</tbody>
</table>

An IPv6 target with two unicast addresses, four Multicast address and five NDP entries needs approximately 660 bytes additional RAM. For detailed information about the configuration and the memory requirements for each TCP/UDP connection, refer to Configuring embOS/IP on page 525.

The required memory is taken from the memory pool of the stack. For further information about how to increase the memory pool, refer to IP_AssignMemory on page 81.
Chapter 24

Web server (Add-on)

The embOS/IP Web server is an optional extension to embOS/IP. The Web server can be used with embOS/IP or with a different TCP/IP stack. All functions that are required to add a Web server task to your application are described in this chapter.
24.1 embOS/IP Web server

The embOS/IP Web server is an optional extension which adds the HTTP protocol to the stack. It combines a maximum of performance with a small memory footprint. The Web server allows an embedded system to present Web pages with dynamically generated content. It comes with all features typically required by embedded systems: multiple connections, authentication, forms and low RAM usage. RAM usage has been kept to a minimum by smart buffer handling.

The Web server implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the Web server with embOS/IP. The standard application consists of two files. IP_WebserverSample.c and Webserver_DynContent.c. IP_WebserverSample.c fits for the most applications without modifications. Webserver_DynContent.c includes the dynamic parts of our sample application, like virtual files, CGI functions, etc.</td>
</tr>
<tr>
<td>.\Config\</td>
<td>Contains the Web server configuration file. Refer to Web server configuration on page 603 for detailed information.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the Web server sources, IP_Webserver.c, IP_Webserver.h and IP_UTIL_BASE64.c, IP_UTIL.h.</td>
</tr>
<tr>
<td>.\IP\FS\</td>
<td>Contains the sources for the file system abstraction layer and the read-only file system. Refer to File system abstraction layer on page 1206 for detailed information.</td>
</tr>
<tr>
<td>.\Windows\Webserver\</td>
<td>Contains the source, the project files and an executable to run embOS/IP Web server on a Microsoft Windows host. Refer to Using the Web server sample on page 579 for detailed information.</td>
</tr>
</tbody>
</table>
24.2 Feature list

- Low memory footprint.
- Dynamic Web pages.
- Authentication supported (Basic and Digest).
- Forms: POST and GET support.
- Multiple connections supported.
- JavaScript supported.
- AJAX supported.
- SSE supported.
- REST supported.
- r/o file system included.
- HTML to C converter included.
- Independent of the file system: any file system can be used.
- Independent of the TCP/IP stack: any stack with sockets can be used.
- Demo with authentication, various forms, dynamic pages included.
- Project for executable on PC for Microsoft Visual Studio included.
24.3 Requirements

TCP/IP stack
The embOS/IP Web server requires a TCP/IP stack. It is optimized for embOS/IP, but any RFC-compliant TCP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and an implementation which uses the socket API of embOS/IP.

Multi tasking
The Web server needs to run as a separate thread. Therefore, a multi tasking system is required to use the embOS/IP Web server.
24.4 HTTP backgrounds

It is a communication protocol originally designed to transfer information via hypertext pages. The development of HTTP is coordinated by the IETF (Internet Engineering Task Force) and the W3C (World Wide Web Consortium). The current protocol version is 1.1.

24.4.1 HTTP communication basics

HTTP is a challenge and response protocol. A client initiates a TCP connection to the Web server and sends a HTTP request. A HTTP request starts with a method token. \[RFC 2616\] defines 8 method tokens. The method token indicates the method to be performed on the requested resource. embOS/IP Web server supports all methods which are typically required by an embedded Web server.

<table>
<thead>
<tr>
<th>HTTP method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>The GET method means that it retrieves whatever information is identified by the Request-URI.</td>
</tr>
<tr>
<td>HEAD</td>
<td>The HEAD method means that it retrieves the header of the content which is identified by the Request-URI.</td>
</tr>
<tr>
<td>POST</td>
<td>The POST method submits data to be processed to the identified resource. The data is included in the body of the request.</td>
</tr>
</tbody>
</table>

The following example shows parts of a HTTP session, where a client (for example, 192.168.1.75) asks the embOS/IP Web server for the hypertext page example.html. The request is followed by a blank line, so that the request ends with a double newline, each in the form of a carriage return followed by a line feed.

```
GET /example.html HTTP/1.1
Host: 192.168.1.75
```

The first line of every response message is the Status-Line, consisting of the protocol version followed by a numeric status code. The Status-Line is followed by the content-type, the server, expiration and the transfer-encoding. The server response ends with an empty line, followed by length of content that should be transferred. The length indicates the length of the Web page in bytes.

```
HTTP/1.1 200 OK
```
Thereafter, the Web server sends the requested hypertext page to the client. The zero at the end of the Web page followed by an empty line signalizes that the transmission of the requested Web page is complete.

```html
<html>
<head>
  <title>embOS/IP examples</title>
</head>
<body>
  <center>
    <h1>Website: example.htm</h1>
  </center>
</body>
</html>
```

### 24.4.2 HTTP status codes

The first line of a HTTP response is the Status-Line. It consists of the used protocol version, a status code and a short textual description of the Status-Code. The Status-Code element is a 3-digit integer result code of the attempt to understand and satisfy the request.

The first digit of the Status-Code defines the class of response. The last two digits do not have any categorization role. There are 5 values for the first digit:

- 1xx: Informational - Request received, continuing process.
- 2xx: Success - The action was successfully received, understood, and accepted.
- 3xx: Redirection - Further action must be taken in order to complete the request.
- 4xx: Client Error - The request contains bad syntax or cannot be fulfilled.
- 5xx: Server Error - The server failed to fulfill an apparently valid request.

Refer to [RFC 2616](https://tools.ietf.org/html/rfc2616) for a complete list of defined status-codes. embOS/IP Web server supports a subset of the defined HTTP status codes. The following status codes are implemented:

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>OK. The request has succeeded.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The request requires user authentication.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The server has not found anything matching the Request-URI.</td>
</tr>
<tr>
<td>501</td>
<td>Not implemented. The server does not support the HTTP method.</td>
</tr>
<tr>
<td>503</td>
<td>Service unavailable. The server is currently unable to handle the request due to a temporary overloading of the server.</td>
</tr>
</tbody>
</table>
24.5 Using the Web server sample

Ready to use examples for Microsoft Windows and embOS/IP are supplied. If you use another TCP/IP stack, the sample IP_WebserverSample.c has to be adapted.

The Web server itself does not handle multiple connections. This is part of the application and is included in the IP_WebserverSample.c sample.

The sample application opens a port which listens on port 80 until an incoming connection is detected in a parent task that accepts new connections (or rejects them if no more connections can be accepted).

For each accepted client connection, the parent task creates a child task running IP_WEBS_ProcessEx() in a separated context that will then process the request of the connected client (for example a browser). This way the parent task is ready to handle further incoming connections on port 80.

Therefore the sample uses n client connections + one for the parent task.

Some browsers may open multiple connections and do not even intend to close the connection. They rather keep the connections open for further data that might be requested. To give other clients a chance, a special handling is implemented in the Web server.

The embOS/IP Web server has two functions for processing a connection in a child task:

- IP_WEBS_ProcessEx(), that allows a connection to stay open even after all data has been sent from the target. The connection will stay open as long as the client does not close it.
- IP_WEBS_ProcessLastEx(), that will close the connection once the target has sent all data requested. This is used by the Web server sample for the last free connection available. This ensures that at least one connection will be available after it has been served to accept further clients.

In addition to available connections that can be served directly, a feature called “backlogging” can be used.

This means additional connections will be accepted (SYN/ACK is sent from target) but not yet processed. They will be processed as soon as a free connection becomes available once a child task has served the clients request and has been closed. Connections in backlog will be kept active until the client side sends a reset due to a possible timeout in the client.

The example application uses a read-only file system to make Web pages available. Refer to File system abstraction layer on page 1206 for detailed information about the read-only file system.
24.5.1 Using the Web server Windows sample

If you have MS Visual C++ 6.00 or any later version available, you will be able to work with a Windows sample project using embOS/IP Web server. If you do not have the Microsoft compiler, an precompiled executable of the Web server is also supplied.

Building the Web server sample program

Open the workspace Start_Webserver.dsw with MS Visual Studio (for example, double-clicking it). There is no further configuration necessary. You should be able to build the application without any error or warning message.

The server uses the IP address of the host PC on which it runs. Open a Web browser and connect by entering the IP address of the host (127.0.0.1) to connect to the Web server.

24.5.2 Running the Web server example on target hardware

The embOS/IP Web server sample application should always be the first step to check the proper function of the Web server with your target hardware.

Add all source files located in the following directories (and their subdirectories) to your project and update the include path:

- Application\  
- Config\  
- Inc\  
- IP\  
- IP\IP_FS\FS_RO\  
- IP\IP_FS\FS_RO\Generated\  

It is recommended that you keep the provided folder structure.

The sample application can be used on the most targets without the need for changing any of the configuration flags. The server processes up to 22 connections using the default configuration.

**Note:** 22 connections means that the target can handle up to 22 clients in parallel, if every client uses only one connection. Because a single Web browser often attempts to open more than one connection to a Web server to request the files (.gif, .jpeg, etc.) which are included in the requested Web page, the number of possible parallel connected clients is less than the number of possible connections.

The 22 connections split into 20 connections that are available to be kept in the backlog of a socket (which means that up to 20 connections wait to be fetched by the application with an accept() and up to 2 connections currently processed.

Every connection is handled in an separate task. Therefore, the Web server uses up to three tasks in the default configuration, one task which listens on port 80 and accepts connections and two tasks to process the accepted connections. To modify the number of connections, only the macro MAX_CONNECTIONS has to be modified.

The most of the supplied sample Web pages include dynamic content, refer to Dynamic content on page 582 for detailed information about the implementation of dynamic content.
24.5.3 Changing the file system type

By default, the Web server uses the supplied read-only file system. If a real file system like emFile should be used to store the Web pages, you have to modify the function _WebServerParentTask() of the example IP_WebserverSample.c. Excerpt from IP_WebserverSample.c:

```c
/*********************************************************************
*       _WebServerParentTask
*
*/
static void _WebServerParentTask(void) {
    struct sockaddr Addr;
    struct sockaddr_in InAddr;
    U32 Timeout;
    long hSockListen;
    long hSock;
    int AddrLen;
    int i;
    int t;
    int t0;
    int r;
    WEB_SIZES BufferSizes;
    Timeout = IDLE_TIMEOUT;
    IP_WEBS_SetFileInfoCallback(&_pfGetFileInfo);
    // Assign file system
    // _pFS_API = &IP_FS_ReadOnly; // To use a a real filesystem like emFile
    // replace this line.
    // _pFS_API = &IP_FS_FS; // Use emFile
}
```

The usage of the read-only file system is configured with the following line:

```
_pFS_API = &IP_FS_ReadOnly;
```

To use emFile as file system for your Web server application, add the emFile abstraction layer IP_FS_FS.c to your project and change the line to:

```
_pFS_API = &IP_FS_FS;
```

Refer to File system abstraction layer on page 1206 for detailed information about the emFile and read-only file system abstraction layer.
24.6 Dynamic content

embOS/IP supports different approaches to implement dynamic content in your Web server application. A Common Gateway Interface (CGI) like interface for static HTML pages with dynamic elements and virtual files which are completely generated from the application.

24.6.1 Common Gateway Interface (CGI)

A Common Gateway Interface (CGI) like interface is used to implement dynamic content in Web pages. Every Web page will be parsed by the server each time a request is received. The server searches the Web page for a special tag. In the default configuration, the searched tag starts `<!--` and ends with `-->`. The tag will be analyzed and the parameter will be extracted. This parameter specifies a server-side command and will be given to the user application, which can handle the command. The following screenshot shows the example page `index.htm`.

The HTML source for the page includes the following line:

```
<!--#exec cgi="Counter"-->
```

When the Web page is requested, the server parses the tag and the parameter _Counter_ is searched for in an array of structures of type `WEBS_CGI`. The structure includes a string to identify the command and a pointer to the function which should be called if the parameter is found.

```
typedef struct {
    const char * sName; // e.g. "Counter"
    void (*pf)(WEBS_OUTPUT * pOutput, const char * sParameters, const char * sValue);
} WEBS_CGI;
```
In the example, **Counter** is a valid parameter and the function `callback_ExecCounter` will be called. You need to implement the `WEBS_CGI` array and the callback functions in your application.

```c
static const WEBS_CGI _aCGI[] = {
    { "Counter"    ,  _callback_ExecCounter  },
    { "GetOSInfo"  ,  _callback_ExecGetOSInfo },
    { "GetIPAddr"  ,  _callback_ExecGetIPAddr},
    { NULL }
};
```

`_callback_ExecCounter()` is a simple example of how to use the CGI feature. It returns a string that includes the value of a variable which is incremented with every call to `callback_ExecCounter()`.

```c
static void _callback_ExecCounter( WEBS_OUTPUT * pOutput,
    const char* sParameters,
    const char* sValue ) {
    char ac[80];
    WEBS_USE_PARA(sParameters);
    WEBS_USE_PARA(sValue);
    _Cnt++;  
    SEGGER_snprintf(ac, sizeof(ac),
            "<br><span class="hint">Current page hit count: %lu</span></ul>",
            _Cnt);
    IP_WEBS_SendString(pOutput, ac);
}
```

If the Web page includes the CGI tag followed by an unknown command (for example, a typo like `COunter` instead of `Counter` in the source code of the Web page) an error message will be sent to the client.
24.6.1.1 Add new CGI functions to your Web server application

To define new CGI functions, three things have to be done.

1. Add a new command name which should be used as tag to the WEBS_CGI structure.
   For example: `UserCGI`

   ```c
   static const WEBS_CGI _aCGI[] = {
   { "Counter" , _callback_ExecCounter           },
   { "GetIndex" , _callback_ExecGetIndex          },
   { "UserCGI"  , _callback_ExecUserCGI           },
   { NULL , _callback_DefaultHandler             }
   };
   ```

2. Implement the new function in your application source code.

   ```c
   static void _callback_ExecUserCGI ( WEBS_OUTPUT * pOutput,
                                        const char * sParameters
                                        const char * sValue ) {
   /* Add application code here */
   }
   ```

3. Add the new tag to the source code of your Web page:

   ```html
   <!-- #exec cgi="UserCGI" -->
   ```

24.6.2 Virtual files

embOS/IP supports virtual files. A virtual file is not a real file which is stored in the used file system. It is a function which is called instead. The function generates the content of a file and sends it to the client.

The Web server checks the extension of all requested files, the extension `.cgi` is by default used for virtual files. To change the extension that is used to detect a virtual file, refer to `IP_WEBS_SetFileInfoCallback` on page 641 for detailed information.

The embOS/IP Web server comes with an example (CallVirtualFile.htm) that requests a virtual file. The sample Web page contains a form with two input test fields, named `FirstName` and `LastName`, and a button to transmit the data to the server.

When the button on the Web page is pressed, the file `Send.cgi` is requested. The embOS/IP Web server recognizes the extension `.cgi`, checks if a virtual file with the name `Send.cgi` is defined and calls the defined function. The function in the example is `_callback_SendCGI()` and gets the string `FirstName=Foo&LastName=Bar` as parameter.
In the example, `Send.cgi` is a valid URI and the function `_callback_SendCGI()` will be called.

```c
static const WEBS_VFILES _aVFiles[] = {
    { "Send.cgi", _callback_SendCGI },
    NULL
};
```

The virtual file `Send.cgi` gets two parameters. The strings entered in the input fields `FirstName` and `LastName` are transmitted with the URI. For example, you enter `Foo` in the first name field and `Bar` for last name and push the button. The browser will transmit the following string to our Web server:

```
Send.cgi?FirstName=Foo&LastName=Bar
```

You can parse the string and use it in the way you want to. In the example we parse the string and output the values on a Web page which is build from the function `_callback_CGI_Send()`.

```c
/* *********************************************************************/
/*        _SendPageHeader                                          */
/* Function description: */
/* Sends the header of the virtual file. */
/* The virtual files in our sample application use the same HTML layout. */
/* The only difference between the virtual files is the content and that */
/* each of them use an own title/heading. */
/* */
static void _SendPageHeader(WEBS_OUTPUT * pOutput, const char * sName)
{
    IP_WEBS_SendString(pOutput, "<!DOCTYPE html><html><head><title>");
    IP_WEBS_SendString(pOutput, sName);
    IP_WEBS_SendString(pOutput, "</title>"
); IP_WEBS_SendString(pOutput, "<link href="Styles.css" rel="stylesheet"></head><body><header>”;
    IP_WEBS_SendString(pOutput, sName);
    IP_WEBS_SendString(pOutput, "</header>"
); IP_WEBS_SendString(pOutput, "<div class="content">");
}
/* *********************************************************************/
/*        _SendPageFooter                                          */
/* Function description: */
/* Sends the footer of the virtual file. */
/* The virtual files in our sample application use the same HTML layout. */
/* */
static void _SendPageFooter(WEBS_OUTPUT * pOutput)
{
    IP_WEBS_SendString(pOutput, "</div><br><br><br>");
    IP_WEBS_SendString(pOutput, "<img src="Logo.gif" alt="Segger logo" class="logo">");
    IP_WEBS_SendString(pOutput, "<footer><p><a href="index.htm">Back to main</a></p>”;
    IP_WEBS_SendString(pOutput, "<p>SEGGER Microcontroller GmbH &amp; Co. KG
    || <a href="http://www.segger.com">www.segger.com</a>
    ||<span class="hint">(external link)</span></p></footer></body></html>”
);}
/* *********************************************************************/
/*        _callback_CGI_Send                                       */
/* */
static void _callback_CGI_Send(WEBS_OUTPUT * pOutput, const char * sParameters)
{ int r;
```
const char * pFirstName;
    int     FirstNameLen;
const char * pLastName;
    int     LastNameLen;

// Header of the page
// _SendPageHeader(pOutput, "Virtual file sample");
// Content
//
// IP_WEBS_GetParaValuePtr(sParameters, 0, NULL, 0, &pFirstName, &FirstNameLen);
// IP_WEBS_GetParaValuePtr(sParameters, 1, NULL, 0, &pLastName, &LastNameLen);
if (r == 0) {
    IP_WEBS_SendString(pOutput, "<h3>First name: ");
    IP_WEBS_SendString(pOutput, pFirstName, FirstNameLen);
    IP_WEBS_SendString(pOutput, "</h3>");
    IP_WEBS_SendString(pOutput, "<h3>Last name: ");
    IP_WEBS_SendString(pOutput, pLastName, LastNameLen);
    IP_WEBS_SendString(pOutput, "</h3>");
} else {
    IP_WEBS_SendString(pOutput, "<br>Error!");
}
// Footer of the page
// _SendPageFooter(pOutput);

The output of _callback_CGI_Send() should be similar to:

![Virtual file sample](image)
24.6.3 AJAX

The embOS/IP Web server supports AJAX. AJAX is an acronym for Asynchronous JavaScript and XML. It is the foundation to build responsive and dynamic Web applications, which look and feel like desktop applications. AJAX is a special way to communicate with a Web server. In opposite to the old fashioned synchronous way where every data transmission to or from the server needs a reload of the whole Web page, AJAX works behind the scenes. With AJAX it is possible to grab the data you want and display it instantly in a Web page. No page refreshes needed, no waiting, no flickering in the browser. AJAX works on all major browsers.

AJAX combines some well-known Web techniques like HTML and CSS, JavaScript and XML. From the perspective of a developer the really interesting part AJAX are the XMLHttpRequests. An XMLHttpRequest object is an API available to Web browser scripting languages such as JavaScript and the core component for the asynchronous communication. The name XMLHttpRequest is a little bit misleading, since XMLHttpRequest can be used to send and receive any kind of data, not just XML. In most cases the exchanged data is plain text, HTML or JSON.

To exchange data without a reload of the whole page, you need create an XMLHttpRequest object. The way to create an XMLHttpRequest object is browser dependent. Therefore, it make sense to capsule the creation in a JavaScript function, which tries to handle every browser. An example is listed below:

```javascript
// Create a XMLHttpRequest.
// Tries to handle the different browser implementation

function _CreateRequest () {
    try {
        request = new XMLHttpRequest();
    } catch (tryMS) {
        try {
            request = new ActiveXObject("Msxml2.XMLHTTP");
        } catch (otherMS) {
            try {
                request = new ActiveXObject("Microsoft.XMLHTTP");
            } catch (failed) {
                request = null;
            }
        }
    }
    return request;
}
```

With an XMLHttpRequest object it is easy to exchange data with a Web server. The XMLHttpRequest object only needs an URI which should be requested from the server and a callback function, which will be called as soon as data will be received.

```javascript
// Request the details from the server.

function _GetData (itemName) {
    request = _CreateRequest(); // Create an XMLHttpRequest
    if (request == null) {
        alert("Unable to create request");
        return;
    }
    var url = "./GetData.cgi";
    request.open("GET", url, true);
    request.onreadystatechange = _YourFunction;
    request.send(null);
}
```
In the example `GetData.cgi` is a virtual file, which will be requested from the embOS/IP Web server and `_YourFunction` is registered as callback function. For further information about the implementation of a virtual file, refer to `Virtual files` on page 584.

After setting the callback function, the request has to be sent. `_YourFunction` will be called each time the readyState of the request object changes. To guarantee that the request is complete and the transmission status is ok, the readyState and HTTP status should be checked in your callback function.

```javascript
//
// Request the details from the server.
//
function _DisplayDetails () {
    if (request.readyState == 4) { // Is the request complete ?
        if (request.status == 200) { // Status OK ?
            // Do something with the received data.
        }
    }
}
```

The embOS/IP Web server comes with some sample Web pages to demonstrate how AJAX can be used to get and visualize data from your target.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Products.htm</td>
<td>Simple AJAX sample. The Web page shows pictures of SEGGER middleware products. On click on one of the pictures an XMLHttpRequest is created and additional product related information is requested from the embOS/IP Web server.</td>
</tr>
<tr>
<td>Shares.htm</td>
<td>The sample demonstrates the usage of Server-Sent Events (SSE) and AJAX with the embOS/IP Web server. The displayed stock quotes table is random data generated by the server and updated every second via SSE. The graph is updated via AJAX. Every update of the stock prices table triggers the graph library to request the last 30 stock prices of the selected company to redraw the graph. All stock quotes are fictional. The goal of this example is to demonstrate how simple it is to visualize any kind of data with the embOS/IP Web server. The sample uses the open source JavaScript library RGraph for the visualization of the stock quotes. RGraph is an HTML5 charts library, which uses the MIT license. The latest version of the library can be downloaded from <a href="http://www.rgraph.net/">http://www.rgraph.net/</a>.</td>
</tr>
</tbody>
</table>

All samples are hardware independent and tested with popular Web browsers like Internet Explorer, Firefox and Chrome.

For further information about AJAX, XMLHttpRequest handling, and data visualization we recommend one of the many available reference books.
24.6.4 Server-Sent Events (SSE)

Server-Sent Events (SSE) are an HTML5 technology which enables a Web server to push data to Web pages over HTTP. The Web browser establishes an initial connection, which is used for the Web server updates.

The embOS/IP Web server supports SSE to supply the Web browser with dynamic content. A Web browser can request information via EventSource objects. The idea behind SSE is that the Web server keeps a connection to Web browser open and sends data via this connection whenever it is necessary. This means that the Web browser receives data as a stream without polling. This reduces the HTTP protocol overhead.

To subscribe to an event stream, you have to create an EventSource object and pass it the URL of your stream.

```javascript
if(typeof(EventSource) !== "undefined") {
  var source = new EventSource("SSETime.cgi");
  source.onmessage = function(event) {
    document.getElementById("Time").innerHTML = 
      
      "<h2>" + event.data + "</h2>"
      
    document.getElementById("Time").innerHTML +=
    "The browser gets the system time via a Server-Sent Event (SSE)."
    
    if(r == 0) {    // Data transmitted
      OS_Delay(500);
    } else {
      break;
    }
  }
} else {
  document.getElementById("Time").innerHTML =
    "Sorry, your browser does not support Server-Sent Events (SSE)..."
}
</script>
```

The source code excerpt above creates a new EventSource object. The EventSource objects starts immediately listening for events on the given URL SSETime.cgi. Everytime when the Web browser will receive data, the data will be displayed on the Web page.

SSETime.cgi is implemented in the supplied embOS/IP Web Server sample application (Webserver_DynContent.c). From the perspective of the Web server it is a virtual file. Please refer to Virtual files on page 510 for further information about virtual files. The following excerpt of Webserver_DynContent.c shows the implementation of the virtual file SSETime.cgi.

```c
/* */
/* _callback_CGI_SSETime */
/* */
static void _callback_CGI_SSETime(WEBS_OUTPUT * pOutput, const char * sParameters) {
  int r;
  
  IP_USE_PARA(sParameters);
  
  // Construct the SSE Header
  //
  IP_WEBS_SendHeaderEx(pOutput, NULL, "text/event-stream", 1);
  IP_WEBS_SendString(pOutput, "retry: 1000\n");
  while(1) {
    r = _SendTime((void*)pOutput);
    if (r == 0) {    // Data transmitted
      OS_Delay(500);
    } else {
      break;
    }
  }
}
```
First step to send data as an event stream is to send the MIME type text/event-stream to the Web browser. The Web browser attempts to reconnect to the Web server ~3 seconds after a connection is closed. You can change that timeout by sending a line beginning with retry:, followed by the number of milliseconds to wait before trying to reconnect. The event stream message is build in _SendTime(). After sending the data OS_Delay() suspends the task for 500ms. _SendTime() will be called again after the delay as long as the connection is open.

```c
/*
 *  _SendTime
 *  
 *  Function description:
 *  Sends the system time to the Web browser.
 *  
 *  Return value:
 *  0: Data successfully sent.
 *  -1: Data not sent.
 *  1: Data successfully sent. Connection should be closed.
 */
static int _SendTime(WEBS_OUTPUT * pOutput) {
    int r;
    // Send implementation specific header to client
    IP_WEBS_SendString(pOutput, "data: ");
    IP_WEBS_SendString(pOutput, "System time: ");
    IP_WEBS_SendUnsigned(pOutput, OS_GetTime32(), 10, 0);
    IP_WEBS_SendString(pOutput, "<br>");
    IP_WEBS_SendString(pOutput, "\n\n");  // End of the SSE data
    r = IP_WEBS_Flush(pOutput);
    return r;
}
```

The return value of _SendTime() is checked in _callback_CGI_SSETime(). This is necessary to prove if the data connection is still open. If the connection has been closed by the client, the endless loop will be left and the Web server will end the Web server child task.

SSE is currently not supported by all popular browsers. The following Web browsers support Server-Sent Events natively.

<table>
<thead>
<tr>
<th>Browser</th>
<th>Supported</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Google Chrome</td>
<td>Yes</td>
<td>Starting with Chrome Ver. 27</td>
</tr>
<tr>
<td>MS Internet Explorer</td>
<td>No</td>
<td>——</td>
</tr>
<tr>
<td>Mozilla Firefox</td>
<td>Yes</td>
<td>Starting with Firefox Ver. 30</td>
</tr>
<tr>
<td>Opera</td>
<td>Yes</td>
<td>Starting with Ver. 23</td>
</tr>
<tr>
<td>Safari</td>
<td>Yes</td>
<td>Starting with Ver. 5.1</td>
</tr>
</tbody>
</table>

Since the Microsoft Internet Explorer does not support Server-Sent Events, we use the JavaScript library eventsource.js in our samples to make them also usable with Microsoft Internet Explorer. eventsource.js can be downloaded with the following link:

https://github.com/Yaffle/EventSource/

eventsource.js uses the MIT license. It can be used and modified according to your needs.

The embOS/IP Web server comes with some sample Web pages to demonstrate how SSE can be used to get and visualize data from your target.

24.7 Basic Authentication

"HTTP/1.0", includes the specification for a Basic Access Authentication scheme. The basic authentication scheme is a non-secure method of filtering unauthorized access to resources on an HTTP server, because the user name and password are passed over the network as clear text. It is based on the assumption that the connection between the client and the server can be regarded as a trusted carrier. As this is not generally true on an open network, the basic authentication scheme should be used accordingly.

The basic access authentication scheme is described in:

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The "basic" authentication scheme is based on the model that the client must authenticate itself with a user-ID and a password for each realm. The realm value should be considered an opaque string which can only be compared for equality with other realms on that server. The server will service the request only if it can validate the user-ID and password for the protection space of the Request-URI. There are no optional authentication parameters.

Upon receipt of an unauthorized request for a URI within the protection space, the server should respond with a challenge like the following:

```
WWW-Authenticate: Basic realm="Embedded Web server"
```

where "embOS/IP embedded Web server" is the string assigned by the server to identify the protection space of the Request-URI. To receive authorization, the client sends the user-ID and password, separated by a single colon ("\:" ) character, within a base64 encoded string in the credentials.

If the user agent wishes to send the user-ID "user" and password "pass", it would use the following header field:

```
Authorization: Basic dXNlcjpwYXNz
```
24.7.1 Basic Authentication example

The client requests a resource for which authentication is required:

```
GET /conf/Authen.htm HTTP/1.1
Host: 192.168.11.37
```

The server answers the request with a “401 Unauthorized” status page. The header of the 401 error page includes an additional line WWW-Authenticate. It includes the realm for which the proper user name and password should be transmitted from the client (for example, a Web browser).

```
HTTP/1.1 401 Unauthorized
Date: Mon, 04 Feb 2008 17:00:44 GMT
Server: embOS/IP
Accept-Ranges: bytes
Content-Length: 695
Connection: close
Content-Type: text/html
X-Pad: avoid browser bug
WWW-Authenticate: Basic realm="embOS/IP embedded Web server"

<HTML>
<HEAD><TITLE>401 Unauthorized</TITLE></HEAD>
<BODY>
<H1>401 Unauthorized</H1>
Browser not authentication-capable or authentication failed.<P>
</BODY>
</HTML>
```

The client interprets the header and opens a dialog box to enter the user name and password combination for the realm of the resource.
CHAPTER 24  Basic Authentication

Note: The embOS/IP Web server example always uses the following user name and the password combination:

- **User Name:** user
- **Password:** pass

Enter the proper user name/password combination for the requested realm and confirm with the OK button. The client encodes the user name/password combination to a base64 encoded string and requests the resource again. The request header is enhanced by the following line: `Authorization: Basic dXNlcjpwYXNz`

```
GET /conf/Authen.htm HTTP/1.1
Host: 192.168.11.37
Authorization: Basic dXNlcjpwYXNz
```

The server decodes the user name/password combination and checks if the decoded string matches to the defined user name/password combination of the realm. If the strings are identical, the server delivers the page. If the strings are not identical, the server answers again with a “401 Unauthorized” status page.

```
HTTP/1.1 200 OK
Content-Type: text/html
Server: embOS/IP
Expires: THU, 26 OCT 1995 00:00:00 GMT
Transfer-Encoding: chunked

200
<HTML>
  <HEAD>
    <TITLE>Web server configuration</TITLE>
  </HEAD>
  <BODY>
```
24.7.2 Configuration of the Basic Authentication

The embOS/IP Web server checks the access rights of every resource before returning it. The user can define different realms to separate different parts of the Web server resources. An array of `WEBS_ACCESS_CONTROL` structures has to be implemented in the user application. Refer to `Structure WEBS_ACCESS_CONTROL` on page 681 for detailed information about the elements of the `WEBS_ACCESS_CONTROL` structure. If no authentication should be used, the array includes only one entry for the root path.

```c
WEBS_ACCESS_CONTROL _aAccessControl_Basic[] = {
    { "/" , NULL , NULL , NULL },
    NULL , NULL , NULL , NULL
};
```

To define a realm “conf”, an additional `WEBS_ACCESS_CONTROL` entry has to be implemented.

```c
WEBS_ACCESS_CONTROL _aAccessControl_Basic[] = {
    { "/conf/" , "Login for configuration" , "user:pass", NULL },
    { "/" , NULL , NULL , NULL },
    NULL , NULL , NULL , NULL
};
```

The string “Login for configuration” defines the realm. “user:pass” is the user name/password combination stored in one string.
24.8 Digest Authentication

The Digest Authentication uses the same mechanisms used by the Basic Authentication on page 592 but aims for an improved security level. This is reached by not transferring the password in plain text. In addition it allows to store the password in the web server in hashed form instead of plain text as well.

Digest authentication is based on MD5 hashing to prevent the password being sent plain text. Several variables are known to both sides, transferred in plain text. These known variables are hashed on their own and then being hashed with the password not transferred in plain text on each side. Only if both resulting hashes are equal the server allows access to a protected path.

While MD5 can be brute forced, like many other password based schemes its security is based on the length of the password used. A longer and good randomized password requires more time to be brute forced.

Current MD5 brute force tools running on GPUs are said to be able to brute force a password of 7 characters within 6 minutes. So by adding more characters this will result in much longer run times, multiplied by the number of valid letters in the password and multiplied by the number of characters added.

While Digest Authentication is not the most secure way to prevent unauthorized access to the Web server it can be used to harden the security by combining it with SSL. SSL itself will secure the connection while Digest Authentication prevents plain text passwords to be stored on the target.

24.8.1 Configuration of the Digest Authentication

The Digest Authentication is setup similar to the Configuration of the Basic Authentication on page 595 except that only the username and a hash MD5(Username:Realm:Password) is stored. Refer to Structure WEBS_ACCESS_CONTROL on page 681 for detailed information about the elements of the WEBS_ACCESS_CONTROL structure.

The following example shows the realm “conf” being added for the following parameters:
- Username: “user”
- Password: “pass”
- Realm: “Login for configuration”

```c
WEBS_ACCESS_CONTROL aAccessControl_Digest[] = {
    {"conf/" , "Login for configuration" , "user" , "59294bd4737af087eea5da392cc23c14"},
    { "/" , NULL , NULL , NULL },
    { NULL , NULL , NULL , NULL }
};
```

The Digest Authentication HA1 string can be calculated by using the following example:

```c
char achA1[33];
const char* sUserRealmPass = "User:Login for configuration:Pass";
IP_WEBS_AUTH_DIGEST_CalcHA1(sUserRealmPass, sizeof(sUserRealmPass), &achA1[0]);
achA1[32] = 0;
```

**Note**

Unlike Basic Authentication the Realm can not be changed without recalculating all hashes in the table which would require the password to be known.

Digest Authentication can be enabled for the Web server sample applications such as IP_WebserverSample.c by enabling the WEBS_USE_AUTH_DIGEST define in the WEBS_Conf.h file.
24.9 Form handling

The embOS/IP Web server supports both POST and GET actions to receive form data from a client. POST submits data to be processed to the identified resource. The data is included in the body of the request. GET is normally only used to requests a resource, but it is also possible to use GET for actions in Web applications. Data processing on server side might create a new resource or update existing resources or both.

Every HTML form consists of input items like textfields, buttons, checkboxes, etc. Each of these input items has a name tag. When the user places data in these items in the form, that information is encoded into the form data. Form data is a stream of <name><value> pairs separated by the “&” character. The value each of the input item is given by the user is called the value. The <name><value> pairs are URL encoded, which means that spaces are changed into “+” and special characters are encoded into hexadecimal values. Refer to [RFC 1738] for detailed information about URL encoding. The parsing and decoding of form data is handled by the embOS/IP Web server. Thereafter, the server calls a callback function with the decoded and parsed strings as parameters. The responsibility to implement the callback function is on the user side.

Valid characters for CGI function names:
- A-Z
- a-z
- 0-9
- . _ -

Valid characters for CGI parameter values:
- A-Z
- a-z
- 0-9
- All URL encoded characters
- . _ * ( ) ! $
24.9.1 Simple form processing sample

The following example shows the handling of the output of HTML forms with your Web server application. The example Web page *FormGET.htm* implements a form with three inputs, two text fields and one button.

An excerpt of the HTML code of the Web page as it is added to the server is listed below:

```html
<!--#exec cgi="FirstName"--> <!--#exec cgi="LastName"-->!
<form action="" method="GET">
<label for="FirstName">First name: </label>
<input name="FirstName" type="text" size="30" maxlength="30"
value="<!--#exec cgi="FirstName"-->"&nbsp;
<label for="LastName">Last name: </label>
<input name="LastName" type="text" size="30" maxlength="30"
value="<!--#exec cgi="LastName"-->"&nbsp;
<input type="submit" value="Change">
</form>
```

The action field of the form can specify a resource that the browser should reference when it sends back filled-in form data. If the action field defines no resource, the current resource will be requested again.
If you request the Web page from the embOS/IP Web server and check the source of the page in your Web browser, the CGI parts "<!--#exec cgi="FirstName"-->
and "<!--
#exec cgi="LastName"-->
will be executed before the page will be transmitted to the server, so that in the example the values of the value= fields will be empty strings.

The HTML code of the Web page as seen by the Web browser is listed below:

```html
<!DOCTYPE html>
<html>
<head>
  <title>Virtual file sample</title>
  <link href="Styles.css" rel="stylesheet">
</head>
<body>
<header>Virtual file sample</header>
<div class="content">
  <form action="Send.cgi" method="GET">
    <label for="FirstName">First name: </label>
    <input name="FirstName" type="text" size="30" maxlength="30" value="">
    <label for="LastName">Last name: </label>
    <input name="LastName" type="text" size="30" maxlength="30" value="">
    <input type="submit" value="Change">
  </form>
</div>
<img src="Logo.gif" alt="Segger company logo" class="logo">
<footer>
  <p>
    <a href="index.htm">Back to main</a>
    SEGGER Microcontroller GmbH &amp; Co. KG ||
    <a href="http://www.segger.com">www.segger.com</a>
    (external link)
  </p>
</footer>
</body>
</html>
```

To start form processing, you have to fill in the FirstName and the LastName field and click the Send button. In the example, the browser sends a GET request for the resource referenced in the form and appends the form data to the resource name as an URL encoded string. The form data is separated from the resource name by "?". Every <name>=<value> pair is separated by ".

For example, if you type in the FirstName field John and Doe in the LastName field and confirm the input by clicking the Send button, the following string will be transmitted to the server and shown in the address bar of the browser.

```
http://192.168.11.37/FormGET.htm?FirstName=John&LastName=Doe
```

**Note:** If you use POST as HTTP method, the <name>=<value> pairs are not shown in the address bar of the browser. The <name>=<value> pairs are in this case included in the entity body.

The embOS/IP Web server parses the form data. The <name> field specifies the name of a CGI function which should be called to process the <value> field. The server checks therefore if an entry is available in the WEB_SCGI array.

```c
static const WEBS_CGI _aCGI[] = {
    {"FirstName",     _callback_ExecFirstName},
    {"LastName",      _callback_ExecLastName},
    {NULL}
};
```

If an entry can be found, the specified callback function will be called.
The callback function for the parameter FirstName is defined as follow:

```c
static char _acFirstName[12];

static void _callback_ExecFirstName ( WEBS_OUTPUT * pOutput, const char * sParameters, const char * sValue ) {
    if ( sValue == NULL ) {
        IP_WEBS_SendString ( pOutput, _acFirstName );
    } else {
        _CopyString ( _acFirstName, sValue, sizeof ( _acFirstName ));
    }
}
```

The function returns a string if `sValue` is NULL. If `sValue` is defined, it will be written into a character array. Because HTTP transmission methods GET and POST only transmit the value of filled input fields, the same function can be used to output a stored value of an input field or to set a new value. The example Web page shows after entering and transmitting the input the string Hello John Doe above the input fields until you enter and transmit another name to the server.
24.10 File upload

The embOS/IP Web server supports file uploads from the client. For this to be possible a real file system has to be used and the define `WEBS_SUPPORT_UPLOAD` has to be defined to "1".

From the application side uploading a file in general is the same as for other form data as described in Form handling on page 597. For file uploading a `<form>` field with encoding of type `multipart/form-data` is needed. An upload form field may contain additional input fields that will be parsed just as if using a non upload formular and can be parsed in your callback using `IP_WEBS_GetParaValue()` or by using `IP_WEBS_GetParaValuePtr()`.

24.10.1 Simple form upload sample

The following example shows the handling of file uploads with your Web server application. The example Web page `Upload.htm` implements a form with a file upload field.

```html
<HTML>
  <BODY>
    <CENTER>
      <P>
        <form action="Upload.cgi" method="post" enctype="multipart/form-data">
          <p> Select a file: <input name="Data" type="file">
          </p>
          <input type="submit"><input type="reset">
        </form>
      </P>
    </CENTER>
  </BODY>
</HTML>
```

The action field of the form can specify a resource that the browser should reference when it has finished handling the file upload. If the action field defines no resource, the current resource will be requested again.

To upload a file, you have to select a file by using the browse button and select a file to upload and click the Send button. In the example, the browser sends a POST request for the resource referenced in the form and appends the form and file data in an encoded string.

```html
Select a file: C:\gF Browse.
  Submit Query  Reset

The HTML code of the Web page as it is added to the server is listed below:
```

```html
<HTML>
  <BODY>
    <CENTER>
      <P>
        <form action="Upload.cgi" method="post" enctype="multipart/form-data">
          <p> Select a file: <input name="Data" type="file">
          </p>
          <input type="submit"><input type="reset">
        </form>
      </P>
    </CENTER>
  </BODY>
</HTML>
```

If an entry can be found, the specified callback function will be called.

The callback function for the file `Upload.cgi` is defined as follow:

```c
static const WEBS_VFILES _aVFiles[] = {
   {"Upload.cgi", _callback_CGI_UploadFile },
   { NULL, NULL }
};
```
In addition to the provided form fields from the upload form used two additional entries will be added to the end of the parameter list available for parsing:

- The original filename of the file uploaded
- The status of the upload process. This can be 0: Upload failed or 1: Upload succeeded.

The example Web page shows after the upload has been finished.

Upload of "1.gif" successful!
Go to 1.gif

The source of the Web page as seen by the Web browser is listed below:

```html
<HTML><BODY>
Upload of "1.gif" successful!<br>
<a href="1.gif">Go to 1.gif</a><br>
</BODY></HTML>
```
24.11 Web server configuration

The embOS/IP Web server can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

24.11.1 Web server compile time configuration

The embOS/IP Web server can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define U8, which the preprocessor would replace with unsigned char.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

24.11.2 Web server compile time configuration switches

<table>
<thead>
<tr>

<tr>
<td>N</td>
<td>WEBS_PARA_BUFFER_SIZE</td>
<td>256</td>
<td>Defines the size of the buffer used to store the parameter/value string that is given to a virtual file. If virtual files are not used in your application, remove the definition from <code>WEBS_Conf.h</code> to save RAM. Please refer to <em>Web server runtime configuration</em> on page 605 for further information about the usage.</td>
</tr>
<tr>
<td>N</td>
<td>WEBS_FILENAME_BUFFER_SIZE</td>
<td>64</td>
<td>Defines the size of the buffer used to store the requested URI/filename to access on the filesystem. Please refer to <em>Web server runtime configuration</em> on page 605 for further information about the usage.</td>
</tr>
<tr>
<td>N</td>
<td>WEBS_TEMP_BUFFER_SIZE</td>
<td>256</td>
<td>Defines the size of the TEMP buffer used internally by the Web server.</td>
</tr>
<tr>
<td>N</td>
<td>WEBS_AUTH_BUFFER_SIZE</td>
<td>32</td>
<td>Defines the size of the buffer used to store the authentication string. Refer to <em>Basic Authentication</em> on page 592 for detailed information about authentication.</td>
</tr>
<tr>
<td>B</td>
<td>WEBS_SUPPORT_UPLOAD</td>
<td>0/1</td>
<td>Defines if file upload is enabled. Defaults to 0: Not enabled, for source code shipments and 1: Enabled, for object shipments. If you do not use the upload feature, define <code>WEBS_SUPPORT_UPLOAD</code> to 0.</td>
</tr>
<tr>
<td>N</td>
<td>WEBS_URI_BUFFER_SIZE</td>
<td>0</td>
<td>Defines the size of the buffer used to store the “full URI” of the accessed resource. By default this feature is disabled.</td>
</tr>
<tr>
<td>N</td>
<td>WEBS_MAX_ROOT_PATH_LEN</td>
<td>12</td>
<td>Maximum allowed root path length of the Web server in multiples of a CPU native unit (typically int). If the root path of the Web server is the root of your media you can comment out this define or set it to zero. Example: For the root path “/htdocs” the define needs to be set to at least 9. As this is not a multiple of an int, set it to 12.</td>
</tr>
</tbody>
</table>
Status message Web pages

The status message Web pages are visualizations of the information transmitted to the client in the header of the Web server response. Because these visualizations are not required for the functionality of the Web server, the macros can be empty.

"</BODY>
"</HTML>
" |

24.11.3 Web server runtime configuration

The input buffer, the output buffer, the parameter buffer, the filename buffer and the maximum root path length are runtime configurable. Up to version 2.20h compile time switches WEBS_IN_BUFFER_SIZE, WEBS_OUT_BUFFER_SIZE and WEBS_PARA_BUFFER_SIZE were used to configure the sizes of the buffers. These compile time switches along with new switches like WEBS_MAX_ROOT_PATH_LEN are still available to guarantee compatibility to previous versions and are used as default values for the buffer sizes in applications where the runtime configuration function IP_WEBS_ConfigBufSizes() is not called. For further information, please refer to IP_WEBS_ConfigBufSizes on page 614.
## API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_AddUpload()</td>
<td>Adds the upload functionality to the Web server.</td>
</tr>
<tr>
<td>IP_WEBS_AddFileTypeHook()</td>
<td>This function registers a FileType hook that can be used to extend or overwrite file types stored in _aFileType[].</td>
</tr>
<tr>
<td>IP_WEBS_AddPreContentOutputHook()</td>
<td>This function registers a hook with a call-back that is called before content (including header) is generated by the web server.</td>
</tr>
<tr>
<td>IP_WEBS_AddProgressHook()</td>
<td>This function registers a hook with a call-back that is called on during several progression steps when serving a request.</td>
</tr>
<tr>
<td>IP_WEBS_AddRequestNotifyHook()</td>
<td>This function registers a hook with a call-back that is called on each request to pass some information like URI and METHOD used to the application.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigBufSizes()</td>
<td>Sets the buffer size used by the Web server tasks.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigFindGZipFiles()</td>
<td>Enables checking if a requested file is available gzip compressed.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigRootPath()</td>
<td>This function sets the root path in the filesystem used to serve pages relative from this path.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigUploadRootPath()</td>
<td>Sets the the root path in the filesystem used to upload files relative from this path.</td>
</tr>
<tr>
<td>IP_WEBS_CountRequiredMem()</td>
<td>Counts the memory required for one thread.</td>
</tr>
<tr>
<td>IP_WEBS_Flush()</td>
<td>Flushes the output buffer.</td>
</tr>
<tr>
<td>IP_WEBS_Init()</td>
<td>Initializes the Web server application context.</td>
</tr>
<tr>
<td>IP_WEBS_OnConnectionLimit()</td>
<td>Outputs an error message to the connected client.</td>
</tr>
<tr>
<td>IP_WEBS_Process()</td>
<td>Thread functionality of the web server.</td>
</tr>
<tr>
<td>IP_WEBS_ProcessEx()</td>
<td>Thread functionality of the web server.</td>
</tr>
<tr>
<td>IP_WEBS_ProcessLast()</td>
<td>Thread functionality of the web server.</td>
</tr>
<tr>
<td>IP_WEBS_ProcessLastEx()</td>
<td>Processes a HTTP request of a client and closes the connection thereafter.</td>
</tr>
<tr>
<td>IP_WEBS_Redirect()</td>
<td>Sends a page from the file system to the browser instead of the regular content.</td>
</tr>
<tr>
<td>IP_WEBS_Reset()</td>
<td>Resets internal variables for a clean start of the Web Server.</td>
</tr>
<tr>
<td>IP_WEBS_RetrieveUserContext()</td>
<td>Retrieves a previously stored user context for the current output session.</td>
</tr>
<tr>
<td>IP_WEBS_SendFormattedString()</td>
<td>Sends a string with placeholders that will be filled using SEGGER_vsnprintfEx().</td>
</tr>
<tr>
<td>IP_WEBS_SendHeader()</td>
<td>Outputs a valid HTML header.</td>
</tr>
<tr>
<td>IP_WEBS_SendHeaderEx()</td>
<td>Outputs a valid HTML header.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>IP_WEBS_SendLocationHeader()</td>
<td>Sends a header with a redirection code for the browser.</td>
</tr>
<tr>
<td>IP_WEBS_SendMem()</td>
<td>Sends data to a connected target.</td>
</tr>
<tr>
<td>IP_WEBS_SendString()</td>
<td>Sends a zero-terminated string to a connected target.</td>
</tr>
<tr>
<td>IP_WEBS_SendStringEnc()</td>
<td>Encodes and sends a zero-terminated string to a connected target.</td>
</tr>
<tr>
<td>IP_WEBS_SendUnsigned()</td>
<td>Sends an unsigned value to the client.</td>
</tr>
<tr>
<td>IP_WEBS_SetErrorPageCallback()</td>
<td>Sets a callback that gets executed when an error page is sent.</td>
</tr>
<tr>
<td>IP_WEBS_SetFileInfoCallback()</td>
<td>Sets a callback that can be used to pass file system information about a requested file back to the web server.</td>
</tr>
<tr>
<td>IP_WEBS_SetHeaderCacheControl()</td>
<td>Sets the string to be sent for the cache-control field in the header.</td>
</tr>
<tr>
<td>IP_WEBS_SetUploadFileSystemAPI()</td>
<td>Sets the FS API to use for file uploads.</td>
</tr>
<tr>
<td>IP_WEBS_SetUploadMaxFileSize()</td>
<td>Sets the maximum file size per file that can be uploaded.</td>
</tr>
<tr>
<td>IP_WEBS_StoreUserContext()</td>
<td>Stores a user context for the current output session.</td>
</tr>
</tbody>
</table>

**CGI/virtual file related functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_AddVFileHook()</td>
<td>Registers a function table containing callbacks to check and serve simple virtual file content that is not further processed by the Web server.</td>
</tr>
<tr>
<td>IP_WEBS_CompareFilenameExt()</td>
<td>Checks if the given filename has the given extension.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigSendVFileHeader()</td>
<td>Configures behavior of automatically sending a header containing a MIME type associated to the requested files extension based on an internal list for a requested virtual file.</td>
</tr>
<tr>
<td>IP_WEBS_ConfigSendVFileHookHeader()</td>
<td>Configures behavior of automatically sending a header containing a MIME type associated to the requested files extension based on an internal list for a requested file being served by a registered VFile hook.</td>
</tr>
<tr>
<td>IP_WEBS_DecodeAndCopyStr()</td>
<td>Checks if a string includes url encoded characters, decodes the characters and copies them into destination buffer.</td>
</tr>
<tr>
<td>IP_WEBS_DecodeString()</td>
<td>Checks if a string includes url encoded characters, decodes the characters.</td>
</tr>
<tr>
<td>IP_WEBS_GetDecodedStrLen()</td>
<td>Returns the length of a HTML encoded string when decoded excluding null character.</td>
</tr>
<tr>
<td>IP_WEBS_GetNumParas()</td>
<td>Returns the number of parameters/value pairs.</td>
</tr>
<tr>
<td>IP_WEBS_GetParaValue()</td>
<td>Parses a string for valid parameter/value pairs and writes results in buffer.</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>IP_WEBS_GetParaValuePtr()</td>
<td>Parses a string for valid parameter/value pairs and returns a pointer to the requested parameter and the length of the parameter string without termination.</td>
</tr>
<tr>
<td>IP_WEBS_GetConnectInfo()</td>
<td>Retrieves the connect info that has been passed to the Web Server process function from the application.</td>
</tr>
<tr>
<td>IP_WEBS_GetURI()</td>
<td>Retrieves the requested URI up to the '?' character or the “full URI” including '?' character and all characters up to the next space.</td>
</tr>
<tr>
<td>IP_WEBS.UseRawEncoding()</td>
<td>Overrides the previously selected encoding of the Web Server to use RAW encoding.</td>
</tr>
</tbody>
</table>

**Basic/Digest Authentication related functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_AUTH_DIGEST_CalcHA1()</td>
<td>Calculates the auth digest MD5 hash for the HA1 hash value to use in the WEBS_ACCESS_CONTROL table.</td>
</tr>
<tr>
<td>IP_WEBS_AUTH_DIGEST_GetURI()</td>
<td>Retrieves the URI sent in the client authorization.</td>
</tr>
<tr>
<td>IP_WEBS.GetProtectedPath()</td>
<td>Retrieves the protected path that is tried to access by the current request.</td>
</tr>
<tr>
<td>IP_WEBS.UseAuthDigest()</td>
<td>Use auth digest instead of auth basic for HTTP authentication.</td>
</tr>
</tbody>
</table>

**METHOD extension related functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_METHOD_AddHook()</td>
<td>Registers a callback to serve special content upon call of a METHOD.</td>
</tr>
<tr>
<td>IP_WEBS_METHOD_CopyData()</td>
<td>This function can be called from a METHOD hook callback to copy the received amount of data as stated by the “Content-Length” field of the header.</td>
</tr>
</tbody>
</table>

**WebSocket extension related functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_WEBSOCKET_AddHook()</td>
<td>This function registers a WebSocket hook that can be used to connect to a WebSocket implementation.</td>
</tr>
</tbody>
</table>

**HEADER extension related functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBS_HEADER_AddFieldHook()</td>
<td>Registers a callback that will be notified if the registered header field is received.</td>
</tr>
<tr>
<td>IP_WEBS_HEADER_CopyData()</td>
<td>Copies the requested amount of data from line with the current header field.</td>
</tr>
<tr>
<td>IP_WEBS_HEADER_GetFindToken()</td>
<td>Searches the current header line for a token and copies its value into a buffer.</td>
</tr>
<tr>
<td>IP_WEBS_HEADER_SetCustomFields()</td>
<td>Sets a custom string of header fields to be included with the next header sent.</td>
</tr>
</tbody>
</table>

**Utility functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_UTIL_BASE64_Decode()</td>
<td>Performs BASE-64 decoding according to RFC3548.</td>
</tr>
<tr>
<td>IP_UTIL_BASE64_Encode()</td>
<td>Performs BASE-64 encoding according to RFC3548.</td>
</tr>
<tr>
<td>IP_UTIL_BASE64_EncodeChunk()</td>
<td>Performs chunked BASE-64 encoding according to RFC3548.</td>
</tr>
</tbody>
</table>
### 24.12.1 IP_WEBS_AddUpload()

**Description**

Adds the upload functionality to the Web server.

**Prototype**

```c
int IP_WEBS_AddUpload(void);
```

**Return value**

- 1: Upload added.
- 0: Upload not added. (WEBS_SUPPORT_UPLOAD = 0)

**Additional information**

A real file system like emFile is required to upload files. Calling this function has no effect if the compile time switch WEBS_SUPPORT_UPLOAD is not defined to 1. In library versions of the Web server WEBS_SUPPORT_UPLOAD is always defined to 1.
24.12.2  IP_WEBS_AddFileTypeHook()

Description
This function registers a FileType hook that can be used to extend or overwrite file types stored in _aFileType[].

Prototype

```c
void  IP_WEBS_AddFileTypeHook (       WEBS_FILE_TYPE_HOOK *  pHook ,
                          const  char                 *  sExt ,
                          const  char                 *  sContent );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_FILE_TYPE_HOOK.</td>
</tr>
<tr>
<td>sExt</td>
<td>String containing the extension.</td>
</tr>
<tr>
<td>sContent</td>
<td>String containing the MIME type assigned to the extension.</td>
</tr>
</tbody>
</table>

Additional information

The function can be used to extend or override the basic list of file extension to MIME type correlations included in the Web server. It might be necessary to extend the this list in case you want to serve a yet unknown file format. The header sent for this file in case a client requests it will be generated based on this information.

Refer to Structure WEBS_FILE_TYPE_HOOK on page 687 for detailed information about the structure WEBS_FILE_TYPE_HOOK.

Example

```c
static  WEBS_FILE_TYPE_HOOK _FileTypeHook ;

int  main ( void ) { 
    // Register *.new files to be treated as binary that will
    // be offered to be downloaded by the browser.
    IP_WEBS_AddFileTypeHook (&_FileTypeHook ,  "new" ,  "application/octet-stream" );
}
```
24.12.3 IP_WEBS_AddPreContentOutputHook()

Description

This function registers a hook with a callback that is called before content (including header) is generated by the web server.

Prototype

```c
void IP_WEBS_AddPreContentOutputHook (WEBS_PRE_CONTENT_OUTPUT_HOOK * pHook,
                                      IP_WEBS_pfPreContentOutput pf,
                                      U32 Mask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a resource of WEBS_PRE_CONTENT_OUTPUT_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to execute before content is sent in a response.</td>
</tr>
<tr>
<td>Mask</td>
<td>Mask of Bitwise-OR'd values when to execute the callback:</td>
</tr>
<tr>
<td></td>
<td>• WEBS_PRE_DYNAMIC_CONTENT_OUTPUT</td>
</tr>
</tbody>
</table>

Additional information

This hook can be used to intercept the web server right before sending content to its best knowledge. As all form data has been processed at this time this can be used to decide if all form data is valid like for a user:pass combination processed via a form. For example upon invalid login data it is possible to redirect from within the callback back to the login page using IP_WEBS_Redirect().

Refer to Structure WEBS_PRE_CONTENT_OUTPUT_HOOK on page 689 for detailed information about the structure WEBS_PRE_CONTENT_OUTPUT_HOOK.
### 24.12.4 IP_WEBS_AddProgressHook()

**Description**
This function registers a hook with a callback that is called on during several progression steps when serving a request.

**Prototype**

```c
void IP_WEBS_AddProgressHook (WEBS_PROGRESS_HOOK * pHook,
                             IP_WEBS_pfProgress  pf);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_PROGRESS_HOOK</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to execute on a request.</td>
</tr>
</tbody>
</table>

**Additional information**

A progress hook can be used for example to allocate some memory to store data between form handling callbacks on BEGIN of serving the request. The memory can then be freed again when finally the END progress is reported and the request is fully progressed.

**Additional information**

Refer to Structure WEBS_PROGRESS_HOOK on page 690 for detailed information about the structure WEBS_PROGRESS_HOOK.
24.12.5  IP_WEBS_AddRequestNotifyHook()

Description
This function registers a hook with a callback that is called on each request to pass some information like URI and METHOD used to the application.

Prototype

```c
void  IP_WEBS_AddRequestNotifyHook ( WEBS_REQUEST_NOTIFY_HOOK *  pHook ,
                          IP_WEBS_pfRequestNotify    pf );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_REQUEST_NOTIFY_HOOK</td>
</tr>
<tr>
<td>pf</td>
<td>Callback to execute on a request.</td>
</tr>
</tbody>
</table>

Additional information
Refer to Structure WEBS_REQUEST_NOTIFY_HOOK on page 692 for detailed information about the structure WEBS_REQUEST_NOTIFY_HOOK.
### 24.12.6 IP_WEBS_ConfigBufSizes()

**Description**
Sets the buffer size used by the Web server tasks.

**Prototype**

```c
void IP_WEBS_ConfigBufSizes(WEBS_BUFFER_SIZES * pBufferSizes);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBufferSizes</td>
<td>Configuration of buffer sizes.</td>
</tr>
</tbody>
</table>

**Additional information**

The structure `WEBS_BUFFER_SIZES` is defined as follow:

```c
typedef struct WEBS_BUFFER_SIZES {
    U32 NumBytesInBuf;
    U32 NumBytesOutBuf;
    U32 NumBytesFilenameBuf;
    U32 MaxRootPathLen;
    U32 NumBytesParaBuf;
} WEBS_BUFFER_SIZES;
```

Since version 3.00, the buffers used by the Web server are runtime configurable. Earlier versions of the Web server used compile time switches to define the buffer sizes. If `IP_WEBS_ConfigBufSizes()` will not be called, the values of the compile time switches will be used to configure the buffer sizes.

We recommend at least 256 bytes for the input buffer and 512 bytes for the output buffer. If virtual files are not used in your application, the parameter buffer and others can be set to 0 to save RAM.
24.12.7  IP_WEBS_ConfigFindGZipFiles()

Description
Enables checking if a requested file is available gzip compressed.

Prototype

```c
void IP_WEBS_ConfigFindGZipFiles(const char * sExtension,
                                 int     ReplaceLastChar);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sExtension</td>
<td>Extension including period letter to add to the end of the URI requested. The resulting URI will be tried to open and sent back gzip compressed.</td>
</tr>
<tr>
<td>ReplaceLastChar</td>
<td>Replace the last character of the requested URI with the first character of the extension.</td>
</tr>
</tbody>
</table>

Additional information

The browser needs to accept gzip compressed content and will tell the web server if this is supported.

Only files that do not contain dynamic content can be used. When enabled and allowed by the browser, a gzip compressed version of the requested file is tried to be opened. If this fails the original filename is tried.

Examples:

- URI = “events.js”; sExtension = “.gz”; ReplaceLastChar = 0; => “events.js.gz”
- URI = “events.js”; sExtension = “z”; ReplaceLastChar = 0; => “events.jsz”
- URI = “events.js”; sExtension = “z”; ReplaceLastChar = 1; => “events.jz”
24.12.8   IP_WEBS_ConfigRootPath()

Description
This function sets the root path in the filesystem used to serve pages relative from this path.

Prototype
int IP_WEBS_ConfigRootPath(const char * sRootPath);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sRootPath</td>
<td>Root path to prepend to URI.</td>
</tr>
</tbody>
</table>

Return value
0    O.K.
1    Error.

Additional information
By default the root path used is the root path of your filesystem. Configuring a root path can be used to separate the Web server from other services like an FTP server root folder. A classic use sample would be that all Web pages are stored in the subfolder "/httpdocs". In this case you can call IP_WEBS_ConfigRootPath("/httpdocs") to load all Web pages relative from this folder in your filesystem instead from the root folder of your filesystem.

Other services like an FTP server can be used to grant access to the root folder of your filesystem to allow access to the /httpdocs subfolder and other files in your filesystem as well.

The root path can be as long as the maximum root path length configured. If IP_WEBS_ConfigBufSizes() will not be called to set the maximum root path length, the default WEBS_MAX_ROOT_PATH_LEN will be used.
24.12.9  IP_WEBS_ConfigUploadRootPath()

Description
Sets the root path in the filesystem used to upload files relative from this path.

Prototype

```c
int IP_WEBS_ConfigUploadRootPath(const char * sUploadRootPath);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sUploadRootPath</td>
<td>Root path to prepend to upload.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>O.K.</td>
</tr>
<tr>
<td>1</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Additional information

By default uploads are placed in the root folder of your filesystem. Configuring an upload root path can be used to redirect uploads to another path like an ”/upload“ folder.

The upload root path can be as long as the maximum path that can be used with the upload filename defined by `WEBS_UPLOAD_FILENAME_BUFFER_SIZE` (minus 1 byte for string termination).
24.12.10  IP_WEBS_CountRequiredMem()

Description
Counts the memory required for one thread. This can be used to determine the total required memory pool size for a configuration.

Prototype

\[
\text{U32 IP_WEBS_CountRequiredMem(WEBS_CONTEXT * pContext);}\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Context keeping track of configured settings. Can be NULL.</td>
</tr>
</tbody>
</table>

Return value
Amount of memory required for internals for handling one thread.

Additional information
In addition to the memory requirement calculated for the Web server internals some additional memory might be required for managing a memory pool.
24.12.11 IP_WEBS_Flush()

Description
Flushes the output buffer.

Prototype

```c
int IP_WEBS_Flush(WEBS_OUTPUT * pOutput);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Pointer to the WEBS_OUTPUT structure.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Data transmitted, connection will be closed.</td>
</tr>
<tr>
<td>0</td>
<td>Data transmitted, connection will be kept open after transmission.</td>
</tr>
<tr>
<td>-1</td>
<td>Error. Data not transmitted, connection will be closed.</td>
</tr>
</tbody>
</table>

Additional information

Normally, the stack handles all the data transmission. IP_WEBS_Flush() should only be used in special use cases like implementing Server-Sent Events, where data transmission should be done immediately.
24.12.12 IP_WEBS_Init()

Description
Initializes the Web server application context. Has to be called if IP_WEBS_ProcessEx() and IP_WEBS_ProcessLastEx() are used for the task handling.

Prototype

```
void IP_WEBS_Init( WEBS_CONTEXT * pContext,
const WEBS_IP_API * pIP_API,
const WEBS_SYS_API * pSYS_API,
const IP_FS_API * pFS_API,
const WEBS_APPLICATION * pApplication);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Application specific Web server context.</td>
</tr>
<tr>
<td>pIP_API</td>
<td>Pointer to a structure holding the IP related API functions.</td>
</tr>
<tr>
<td>pSYS_API</td>
<td>Pointer to a structure holding the system related API functions.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Pointer to a structure holding the file system related API functions.</td>
</tr>
<tr>
<td>pApplication</td>
<td>Web server application settings.</td>
</tr>
</tbody>
</table>

Additional information

The parameter pContext is a structure holding all the required function pointers to the routines used to send and receive bytes from/to the client, access the file system, allocate and free memory, etc.

```c
typedef struct WEBS_CONTEXT {
    const WEBS_IP_API * pIP_API;
    const WEBS_SYS_API * pSYS_API;
    const IP_FS_API * pFS_API;
    const WEBS_APPLICATION * pApplication;
    void * pWebsPara;
    void * pUpload;
} WEBS_CONTEXT;
```

WEBS_IP_API includes all functions, which are required for the used IP stack and is defined as follow:

```c
typedef struct WEBS_IP_API {
    IP_WEBS_tSend pfSend;
    IP_WEBS_tReceive pfReceive;
} WEBS_IP_API;
```

```c
typedef int (*IP_WEBS_tSend) (const unsigned char * pData,
                          int len,
                          void *pConnectInfo );

typedef int (*IP_WEBS_tReceive) (const unsigned char * pData,
                                int len,
                                void *pConnectInfo );
```

The send and receive functions should return the number of bytes successfully sent/received to/from the client. The pointer pConnectInfo is passed to the send and receive routines. It can be used to pass a pointer to a structure containing connection information or to pass a socket number.
WEBS_SYS_API includes all functions, which are required to allocate and free memory and is defined as follow:

```c
typedef struct WEBS_SYS_API {
    IP_WEBS_tAlloc pfAlloc;
    IP_WEBS_tFree pfFree;
} WEBS_SYS_API;

defined as follow:

typedef void *(IP_WEBS_tAlloc) (U32 NumBytesReq);
typedef void *(IP_WEBS_tFree) (void *p);
```

The alloc function returns a void pointer to the allocated space, or NULL if there is insufficient memory available.

For details about the parameter pFS_API and the IP_FS_API structure, refer to File system abstraction layer on page 1206. For details about the parameter pApplication and the WEBS_APPLICATION structure, refer to Structure WEBS_APPLICATION on page 682.

The pWebsPara and pUpload should not be changed. The stack fills the structures, if necessary.

IP_WEBS_Init() has to be called if IP_WEBS_ProccessEx() and IP_WEBS_ProcessLastEx() are used for the connection handling. Refer to IP_WEBS_ProcessEx on page 626 and IP_WEBS_ProcessLastEx on page 628 for detailed information.

Example

```c
/* Excerpt from IP(WebserverSample.c)*/
/*********************************************************************
*       _WebServerChildTask
*       */
static void _WebServerChildTask(void *pContext) {
    WEBS_CONTEXT ChildContext;
    long hSock;
    int Opt;

    hSock    = (long)pContext;
    Opt      = 1;
    setsockopt(hSock, SOL_SOCKET, SO_KEEPALIVE, &Opt, sizeof(Opt));

    // Initialize the context of the child task.
    // IP_WEBS_Init(&ChildContext, &_Webs_IP_API, &_FS_API, &_Application);
    if (_ConnectCnt < MAX_CONNECTIONS) {
        IP_WEBS_ProcessEx(&ChildContext, pContext, NULL);
    } else {
        IP_WEBS_ProcessLastEx(&ChildContext, pContext, NULL);
    }
    _closesocket(hSock);
    OS_EnterRegion();
    _AddToConnectCnt(-1);
    OS_Terminate(0);
    OS_LeaveRegion();
}

/************************************************************************
*       _WebServerParentTask
*       */
static void _WebServerParentTask(void) {
    struct sockaddr Addr;
    struct sockaddr_in InAddr;
    U32 Timeout;
    long hSockListen;
    long hSock;
    int AddrLen;
    int i;
```
```c
int t;
int t0;
WEB_API Web_API;
WEB_SYS_API Web_SYS_API;
WEB_BUF_SIZES BufferSizes;

Timeout = IDLE_TIMEOUT;
IP_WEB_SET_FILEINFO_CALLBACK(& _pfGetFileInfo);
//
// Assign file system
//
_pFS_API = & I_P_FS_ReadOnly; // To use a real filesystem like emFile
// replace this line.
// _pFS_API = & I_P_FS; // Use emFile
// IP_WEB_ADD_UPLOAD(); // Enable upload
//
// Configure buffer size.
//
IP_MEMSET(& BufferSizes, 0, sizeof(BufferSizes));
BufferSizes.NumBytesInBuf = WEB_IN_BUFFER_SIZE;
//
// Use max. MTU configured for the last interface added minus worst
// case IPv4/TCP/VLAN headers. Calculation for the memory pool
// is done under assumption of the best case headers with - 40 bytes.
//
BufferSizes.NumBytesOutBuf = IP_TCP_GET_MTU(_IFaceId) - 72;
BufferSizes.NumBytesParaBuf = WEB_PARA_BUFFER_SIZE;
BufferSizes.NumBytesFilenameBuf = WEB_FILENAME_BUFFER_SIZE;
BufferSizes.MaxRootPathLen = WEB_MAX_ROOT_PATH_LEN;
//
// Configure the size of the buffers used by the Webserver child tasks.
//
IP_WEB_CONFIG_BUF_SIZES(& BufferSizes);
//
// Give the stack some more memory to enable the dynamical memory
// allocation for the Web server child tasks
//
IP_ADD_MEMORY(_aPool, sizeof(_aPool));
//
// Get a socket into listening state
//
hSockListen = socket(AF_INET, SOCK_STREAM, 0);
if (hSockListen == SOCKET_ERROR) {
    while(1); // This should never happen!
}
memset(& InAddr, 0, sizeof(InAddr));
InAddr.sin_family = AF_INET;
InAddr.sin_port = htons(80);
InAddr.sin_addr.s_addr = INADDR_ANY;
bind(hSockListen, (struct sockaddr *)& InAddr, sizeof(InAddr));
listen(hSockListen, BACK_LOG);
//
// Loop once per client and create a thread for the actual server
//
do {
    Next:
//
// Wait for an incoming connection
//
hSock = 0;
Addrlen = sizeof(Addr);
if ((hSock = accept(hSockListen, &Addr, &Addrlen)) == SOCKET_ERROR) {
    continue; // Error
}
//
// Create server thread to handle connection.
// If connection limit is reached, keep trying for some time before giving up
// and outputting an error message
//
t0 = OS_GET_TIME32() + 1000;
do {
    if (_ConnectCnt < MAX_CONNECTIONS) {
        for (i = 0; i < MAX_CONNECTIONS; i++) {
            U8 r;
            r = OS_LS_TASK(& _aWebTasks[i]);
            if (r == 0) {
```
setsockopt(hSock, SOL_SOCKET, SO_RCVTIMEO, &Timeout, sizeof(Timeout));
OS_CREATETASK_EX(&_aWebTasks[i], "Webserver Child", _WebServerChildTask,
    TASK_PRIO_WEB(child), _aWebStacks[i], (void *)hSock);
    _AddToConnectCnt(1);
    goto Next;
}
}
}

// Check time out
//
t = OS_GetTime32();
if ((t - t0) > 0) {
    IP_WEBS_OnConnectionLimit(_Send, _Recv, (void*)hSock);
    _closesocket(hSock);
    break;
}
OS_Delay(10);
while(1);
} while(1);
} while(1);
24.12.13  IP_WEBS_OnConnectionLimit()

**Description**
Outputs an error message to the connected client.

**Prototype**

```c
void IP_WEBS_OnConnectionLimit(IP_WEBS_tSend pfSend, IP_WEBS_tReceive pfReceive, void *pConnectInfo);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfSend</td>
<td>Pointer on the function used to send.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Pointer on the function used to receive.</td>
</tr>
<tr>
<td>pConnectInfo</td>
<td>Pointer on the connection info (typically the socket).</td>
</tr>
</tbody>
</table>

**Additional information**

This function is typically called by the application if the connection limit is reached. Refer to IP_WEBS_Process() and IP_WEBS_ProcessLast() for further information.

**Example**

Pseudo code:

```c
// Call IP_WEBS_Process() or IP_WEBS_ProcessLast() if multiple or just
// one more connection is available
//
do {
  if (NumAvailableConnections > 1) {
    IP_WEBS_Process();
    return;
  } else if (NumAvailableConnections == 1) {
    IP_WEBS_ProcessLast();
    return;
  }
  Delay();
} while (!Timeout)
//
// No connection available even after waiting => Output error message
//
IP_WEBS_OnConnectionLimit();
```
24.12.14 IP_WEBS_Process()

Description
Thread functionality of the web server. Returns when the connection has been handled or an error occurred.

Prototype

```c
int IP_WEBS_Process(       IP_WEBS_tSend      pfSend ,
                        IP_WEBS_tReceive   pfReceive ,
                        void              *  pConnectInfo ,
                        const  IP_FS_API        *  pFS_API ,
                        const  WEBS_APPLICATION *  pApplication );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfSend</td>
<td>Pointer to the function to be used by the server to send data to the client.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Pointer to the function to be used by the server to receive data from the client.</td>
</tr>
<tr>
<td>pConnectInfo</td>
<td>Connection info (typically socket handle).</td>
</tr>
<tr>
<td>pFS_API</td>
<td>API for file system operations.</td>
</tr>
<tr>
<td>pApplication</td>
<td>Web Server application settings.</td>
</tr>
</tbody>
</table>

Return value

- 1: Connection detached.
- 0: O.K.
- < 0: Error.

Additional information

A connection detached return value means that an additional functionality like WebSockets has been enabled and the connection context has been dispatched to another resource and should therefore not be closed by the web server thread.

The following types are used as function pointers to the routines used to send and receive bytes from/to the client:

```c
typedef int (*IP_WEBS_tSend)( const unsigned char * pData ,
                              int     len ,
                              void *  pConnectInfo );

typedef int (*IP_WEBS_tReceive)( const unsigned char * pData ,
                                 int     len ,
                                 void *  pConnectInfo );
```

The send and receive functions should return the number of bytes successfully sent/received to/from the client. The pointer `pConnectInfo` is passed to the send and receive routines. It can be used to pass a pointer to a structure containing connection information or to pass a socket number. For details about the parameter `pFS_API` and the `IP_WEBS_FS_API` structure, refer to File system abstraction layer on page 868. For details about the parameter `pApplication` and the `WEBS_APPLICATION` structure, refer to Structure `WEBS_APPLICATION` on page 682.

Refer to IP_WEBS_ProcessLast on page 627 and IP_WEBS_OnConnectionLimit on page 624 for further information.
24.12.15 IP_WEBS_ProcessEx()

Description
Thread functionality of the web server. Returns when the connection has been handled or an error occurred.

Prototype

```c
int IP_WEBS_ProcessEx(       WEBS_CONTEXT * pContext,
                           void          * pConnectInfo,
                           const  char          * sRootPath );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Context keeping track of configured settings.</td>
</tr>
<tr>
<td>pConnectInfo</td>
<td>Connection info (typical socket handle).</td>
</tr>
<tr>
<td>sRootPath</td>
<td>String with the root path to use for HTML pages. Example: “/httpdocs”</td>
</tr>
</tbody>
</table>

Return value

- 1: Connection detached.
- 0: O.K.
- < 0: Error.

Additional information

IP_WEBS_ProcessEx() is a more flexible version of IP_WEBS_Process() and should be used instead. The parameter pContext is a structure holding all the required function pointers to the routines used to send and receive bytes from/to the client, access the file system, allocate and free memory, etc.

It has to be initialized before usage. Refer to IP_WEBS_Init() for further information.

Refer to IP_WEBS_ProcessLastEx() and IP_WEBS_OnConnectionLimit() for further information about the thread handling of the Web server.

A connection detached return value means that an additional functionality like WebSockets has been enabled and the connection context has been dispatched to another resource and should therefore not be closed by the web server thread.
24.12.16  IP_WEBS_ProcessLast()

Description
Thread functionality of the web server.

Prototype

```c
int IP_WEBS_ProcessLast(       IP_WEBS_tSend       pfSend,       
   IP_WEBS_tReceive       pfReceive,       
   void              * pConnectInfo,       
   const IP_FS_API        * pFS_API,       
   const WEBS_APPLICATION * pApplication );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfSend</td>
<td>Function pointer to socket send routine.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Function pointer to socket receive routine.</td>
</tr>
<tr>
<td>pConnectInfo</td>
<td>Connection info (typical socket handle).</td>
</tr>
<tr>
<td>pFS_API</td>
<td>API for file system operations.</td>
</tr>
<tr>
<td>pApplication</td>
<td>Web Server application settings.</td>
</tr>
</tbody>
</table>

Return value

- 1  Connection detached.
- 0  O.K.
- < 0 Error.

Additional information

This is typically called for the last available connection. In contrast to `IP_WEBS_Process()`, this function closes the connection as soon as the command is completed in order to not block the last connection longer than necessary and avoid Connection-limit errors.

A connection detached return value means that an additional functionality like WebSockets has been enabled and the connection context has been dispatched to another resource and should therefore not be closed by the web server thread.

The following types are used as function pointers to the routines used to send and receive bytes from/to the client:

```c
typedef int (*IP_WEBS_tSend) (const unsigned char * pData,       
                             int     len,       
                             void   * pConnectInfo);

typedef int (*IP_WEBS_tReceive) (const unsigned char * pData,       
                               int    len,       
                               void   * pConnectInfo);
```

The send and receive functions should return the number of bytes successfully sent/received to/from the client. The pointer `pConnectInfo` is passed to the send and receive routines. It can be used to pass a pointer to a structure containing connection information or to pass a socket number. For details about the parameter `pFS_API` and the `IP_WEBS_FS_API` structure, refer to `File system abstraction layer` on page 1206. For details about the parameter `pApplication` and the `WEBS_APPLICATION` structure, refer to `Structure WEBS_APPLICATION` on page 682. Refer to `IP_WEBS_Process` on page 625 and `IP_WEBS_OnConnectionLimit` on page 624 for further information.
24.12.17  IP_WEBS_ProcessLastEx()

Description

Processes a HTTP request of a client and closes the connection thereafter.

Prototype

```c
int IP_WEBS_ProcessLastEx(       WEBS_CONTEXT * pContext,
                               void          * pConnectInfo,
                               const  char          * sRootPath );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Context keeping track of configured settings.</td>
<td></td>
</tr>
<tr>
<td>pConnectInfo</td>
<td>Connection info (typical socket handle).</td>
<td></td>
</tr>
<tr>
<td>sRootPath</td>
<td>String with the root path to use for HTML pages. Example: “/httpdocs”</td>
<td></td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>= 1</td>
<td>Connection detached.</td>
</tr>
<tr>
<td>= 0</td>
<td>O.K.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Additional information

Thread functionality of the web server. This is typically called for the last available connection. IP_WEBS_ProcessLastEx() is a more flexible version of IP_WEBS_Process() and should be used instead. In contrast to IP_WEBS_Process(), this function closes the connection as soon as the command is completed in order to not block the last connection longer than necessary and avoid connection-limit errors.

The parameter pContext is a structure holding all the required function pointers to the routines used to send and receive bytes from/to the client, access the file system, allocate and free memory, etc.:

It has to be initialized before usage. Refer to IP_WEBS_Init() for further information.

Refer to IP_WEBS_ProcessLastEx() and IP_WEBS_OnConnectionLimit() for further information about the thread handling of the Web server.

A connection detached return value means that an additional functionality like WebSockets has been enabled and the connection context has been dispatched to another resource and should therefore not be closed by the web server thread.
24.12.18  IP_WEBS_Redirect()

Description
Sends a page from the file system to the browser instead of the regular content. This way a redirect depending on a result can be realized. The MIME type will be determined automatically from the file name or can be overridden.

Prototype

```c
int IP_WEBS_Redirect(       WEBS_OUTPUT * pOutput,
                           const char * sFileName,
                           const char * sMIMEType);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection</td>
</tr>
<tr>
<td>sFileName</td>
<td>FileName of the file to redirect to. Will be used for MIME type recognition for header.</td>
</tr>
<tr>
<td>sMIMEType</td>
<td>MIME type to be used in header. May be NULL.</td>
</tr>
</tbody>
</table>

Return value

- < 0  Error
- = 0  O.K.

Additional information

The function shall only be called if no other data has been sent out before. The page that will be sent is parsed for CGIs the same way as it would be parsed when being directly being accessed by the browser. However the URL accessed by the browser will remain the same and the browser will show the same URL as address.

Example

```c
/***************************************************************************/
*  
* _CGI_Redirect
*/
static void _CGI_Redirect(WEBS_OUTPUT *pOutput, const char *sParameters) {
  IP_WEBS_Redirect(pOutput, "index.htm", NULL); // Redirect back to index
}
```
24.12.19  IP_WEBS_Reset()

Description
Resets internal variables for a clean start of the Web Server.

Prototype

```
void  IP_WEBS_Reset (void);
```

Additional information
As the Web Server is not directly connected to the IP stack itself it can not register to the IP stacks de-initialize process. Once the stack has been de-initialized this routine shall be called before re-initializing the IP stack and using the Web Server again.
24.12.20  IP_WEBS_RetrieveUserContext()

Description
Retrieves a previously stored user context for the current output session.

Prototype

```c
void *IP_WEBS_RetrieveUserContext(WEBS_OUTPUT * pOutput);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
</tbody>
</table>

Return value

Pointer to the previously stored user context or NULL.

Additional information

A user context retrieved will not reset the stored context. The user stored context remains valid until either set to NULL by the user or the connection being closed.

In case a browser reuses an already opened connection the user context is not reset. This can be used to identify a connection reuse or to exchange data within the same connection. It is user responsibility to make sure that the user context is set back to NULL by the last callback if this behavior is not desired.
24.12.21  IP_WEBS_SendFormattedString()

Description
Sends a string with placeholders that will be filled using SEGGER_vsnprintfEx().

Prototype

```
int IP_WEBS_SendFormattedString(   WEBS_OUTPUT * pOutput,
                                    const char * sFormat,
                                    ...);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>sFormat</td>
<td>Formatted string that might contain placeholders.</td>
</tr>
</tbody>
</table>

Return value
Number of characters (without termination) that would have been stored if the buffer had been large enough.

Additional information
Allows sending a string containing placeholders without the need to have the final string created into a temporary buffer in the application. The output buffer is used directly which saves a buffer and avoids unnecessary copy operations from the application to the output buffer.
24.12.22  IP_WEBS_SendHeader

Description
Outputs a valid HTML header.

Prototype

```c
int IP_WEBS_SendHeader( WEBS_OUTPUT * pOutput,
                        const char * sFileName,
                        const char * sMIMEType);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
<tr>
<td>sFileName</td>
<td>String containing the file name including extension to be written to the</td>
</tr>
<tr>
<td></td>
<td>header.</td>
</tr>
<tr>
<td>sMIMETYPE</td>
<td>MIME type to be used in header. If set, sFileName will be ignored.</td>
</tr>
</tbody>
</table>

Return value

= 0    O.K., header sent.

Additional information

This function can be used in case automatically generating and sending a header has been switched off using IP_WEBS_ConfigSendVFileHeader() or IP_WEBS_ConfigSendVFileHookHeader(). Typically this is the first function you call from your callback generating content for a virtual file or a VFile hook registered callback providing content before you send any other data.

Depending on the MIME type used the browser may wait for new data forever if the connection is not closed after all data has been transferred. For example “application/octet-stream” will leave the browser waiting forever if transfer size is not sent in the header. Therefore, IP_WEBS_SendHeader() informs the Web server to close the connection after sending the data.

A typical header may look as follows:

```
HTTP/1.1 200 OK
Content-Type: image/gif
Server: embOS/IP
Expires: 1 JAN 1995 00:00:00 GMT
Transfer-Encoding: chunked
```
24.12.23 IP_WEBS_SendHeaderEx()

**Description**

Outputs a valid HTML header.

**Prototype**

```c
int IP_WEBS_SendHeaderEx(       WEBS_OUTPUT * pOutput,
                               const  char         * sFileName,
                               const  char         * sMIMEType,
                               U8            ReqKeepCon);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
<tr>
<td>sFileName</td>
<td>String containing the file name including extension to be written to the header.</td>
</tr>
<tr>
<td>sMIMEType</td>
<td>MIME type to be used in header. If set, sFileName will be ignored.</td>
</tr>
</tbody>
</table>
| ReqKeepCon     | • 1: If possible, keep connection open after data transmission.  
                 • 0: Close connection, after data transmission.                      |

**Return value**

0   O.K., header sent, Connection will be kept open after transmission.
1   O.K., header sent, Connection will be closed after transmission.

**Additional information**

This function can be used in case automatically generating and sending a header has been switched off using IP_WEBS_ConfigSendVFileHeader() or IP_WEBS_ConfigSendVFileHookHeader(). Typically this is the first function you call from your callback generating content for a virtual file or a VFile hook registered callback providing content before you send any other data.

Depending on the MIME type used the browser may wait for new data forever if the connection is not closed after all data has been transferred. For example “application/octet-stream” will leave the browser waiting forever if transfer size is not sent in the header. Therefore, IP_WEBS_SendHeaderEx() informs the Web server to close the connection after sending the data.
24.12.24 IP_WEBS_SendLocationHeader()

**Description**
Sends a header with a redirection code for the browser.

**Prototype**
```c
void IP_WEBS_SendLocationHeader( WEBS_OUTPUT * pOutput,
                                 const char * sURI,
                                 const char * sCodeDesc);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
<tr>
<td>sURI</td>
<td>URI where to redirect the browser.</td>
</tr>
<tr>
<td>sCodeDesc</td>
<td>Any code and description that supports the “Location: &lt;URI&gt;” field like:</td>
</tr>
<tr>
<td></td>
<td>- “301 Moved Permanently”</td>
</tr>
<tr>
<td></td>
<td>- “302 Found”</td>
</tr>
<tr>
<td></td>
<td>- “303 See Other”</td>
</tr>
</tbody>
</table>

**Additional information**
A redirect like 303 can be used to forward the user to the same page after POST data has been submitted, resulting in no resending of the POST data upon a refresh of the page.
24.12.25  IP_WEBS_SendMem()

Description
Sends data to a connected target.

Prototype

```c
int IP_WEBS_SendMem( WEBS_OUTPUT * pOutput,
                      const char      * s,
                      unsigned        NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Pointer to the WEBS_OUTPUT structure.</td>
</tr>
<tr>
<td>s</td>
<td>Pointer to a memory location that should be transmitted.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes that should be sent.</td>
</tr>
</tbody>
</table>

Return value

0  O.K.
24.12.26  IP_WEBS_SendString()

Description
Sends a zero-terminated string to a connected target.

Prototype

```c
int IP_WEBS_SendString(   WEBS_OUTPUT * pOutput,
                                  const char * s);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Pointer to the WEBS_OUTPUT structure.</td>
</tr>
<tr>
<td>s</td>
<td>Pointer to a string that should be transmitted.</td>
</tr>
</tbody>
</table>

Return value

0  O.K.
24.12.27   IP_WEBS_SendStringEnc()

Description
Encodes and sends a zero-terminated string to a connected target.

Prototype

```c
int IP_WEBS_SendStringEnc(       WEBS_OUTPUT * pOutput,
                                   const char * s);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Pointer to the WEBS_OUTPUT structure.</td>
</tr>
<tr>
<td>s</td>
<td>Pointer to a string that should be transmitted.</td>
</tr>
</tbody>
</table>

Return value

0  O.K.

Additional information

This function encodes the string `s` with URL encoding, which means that spaces are changed into “+” and special characters are encoded to hexadecimal values. Refer to [RFC 1738] for detailed information about URL encoding.
24.12.28   IP_WEBS_SendUnsigned()

Description
Sends an unsigned value to the client.

Prototype

```
int IP_WEBS_SendUnsigned(WEBS_OUTPUT * pOutput,
                        unsigned v,
                        unsigned Base,
                        int NumDigits);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Pointer to the WEBS_OUTPUT structure.</td>
</tr>
<tr>
<td>v</td>
<td>Value that should be sent.</td>
</tr>
<tr>
<td>Base</td>
<td>Numerical base of the value <code>v</code>.</td>
</tr>
<tr>
<td>NumDigits</td>
<td>Number of digits that should be sent. 0 can be used as a wildcard.</td>
</tr>
</tbody>
</table>

Return value

0     O.K.
24.12.29  IP_WEBS_SetErrorPageCallback()

Description
Sets a callback that gets executed when an error page is sent.

Prototype
void IP_WEBS_SetErrorPageCallback(IP_WEBS_pfSendErrorPage pf,
                                 void * pConfig);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pf</td>
<td>Pointer to a callback function to send an error page.</td>
</tr>
<tr>
<td>pConfig</td>
<td>Reserved for future API extension. Use NULL.</td>
</tr>
</tbody>
</table>

Additional information
If the callback returns with WEB_NO_ERROR_PAGE_SENT, the default content of the WEBS_XXX_PAGE define will be sent.

Custom error pages are only supported if the browser supports at least HTTP/1.1 for chunked encoding, for HTTP/1.0 only RAW encoding is available and the default content of the WEB_XXX_PAGE define will be sent.
24.12.30  IP_WEBS_SetFileInfoCallback()

Description
Sets a callback that can be used to pass file system information about a requested file back to the web server.

Prototype

```c
void IP_WEBS_SetFileInfoCallback(IP_WEBS_pfGetFileInfo pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pf</code></td>
<td>Pointer to a callback function.</td>
</tr>
</tbody>
</table>

Additional information

The function can be used to change the default behavior of the Web server. If the file info callback function is set, the Web server calls it to retrieve the file information. The file information are used to decide how to handle the file and to build the HTML header. By default (no file info callback function is set), the Web server parses every file with the extension .htm to check if dynamic content is included; all requested files with the extension .cgi are recognized as virtual files. Beside of that, the Web server sends by default the expiration date of a Web site in the HTML header. The default expiration date (THU, 01 JAN 1995 00:00:00 GMT) is in the past, so that the requested Webpage will never be cached. This is a reasonable default for Web pages with dynamic content. If the callback function returns 0 for DateExp, the expiration date will not be included in the header. For static Webpages, it is possible to add the optional “Last-Modified” header field. The “Last-Modified” header field is not part of the header by default. Refer to Structure IP_WEBS_FILE_INFO for detailed information about the structure IP_WEBS_FILE_INFO.

Example

```c
static void _GetFileInfo(const char * sFilename, IP_WEBS_FILE_INFO * pFileInfo){
int v;
// .cgi files are virtual, everything else is not
//
v = IP_WEBS_CompareFilenameExt(sFilename, ".cgi");
pFileInfo->IsVirtual = v ? 0 : 1;
//
// .htm files contain dynamic content, everything else is not
//
v = IP_WEBS_CompareFilenameExt(sFilename, ".htm");
pFileInfo->AllowDynContent = v ? 0 : 1;
//
// If file is a virtual file or includes dynamic content,
// get current time and date stamp as file time
//
pFileInfo->DateLastMod = _GetTimeDate();
if (pFileInfo->IsVirtual || pFileInfo->AllowDynContent) {
  //
  // Set last-modified and expiration time and date
  //
pFileInfo->DateExp = _GetTimeDate(); // If "Expires" HTTP header field should
  // be transmitted, set expiration date.
} else {
  pFileInfo->DateExp = 0xEE210000; // Expiration far away (01 Jan 2099) // if content is static
}
```
24.12.31 IP_WEBS_SetHeaderCacheControl()

Description
Sets the string to be sent for the cache-control field in the header. The field itself has to be part of the string, e.g.: "Cache-Control: no-cache".

Prototype

```c
void IP_WEBS_SetHeaderCacheControl(const char * sCacheControl);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sCacheControl</td>
<td>Cache control field content.</td>
</tr>
</tbody>
</table>
24.12.32 IP_WEBS_SetUploadFileSystemAPI()

Description
Sets the FS API to use for file uploads.

Prototype

```c
void IP_WEBS_SetUploadFileSystemAPI(const IP_FS_API * pFS_API);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pFS_API</td>
<td>FS API of type IP_FS_API to use.</td>
</tr>
</tbody>
</table>

Additional information

Using different file system APIs for files to serve and files being uploaded can become handy as it allows serving static pages from a read only file system while using a writeable file system for uploads like a new firmware image.
24.12.33  IP_WEBS_SetUploadMaxFileSize()

Description
Sets the maximum file size per file that can be uploaded.

Prototype

```c
void IP_WEBS_SetUploadMaxFileSize(U32 MaxFileSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MaxFileSize</td>
<td>Maximum number of bytes per uploaded file.</td>
</tr>
</tbody>
</table>
24.12.34 IP_WEBS_StoreUserContext()

Description
Stores a user context for the current output session. The user context can be used to exchange data between CGI callbacks of the same connection.

Prototype

```c
void IP_WEBS_StoreUserContext ( WEBS_OUTPUT * pOutput ,
                               void         * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
<tr>
<td>pContext</td>
<td>User context to store.</td>
</tr>
</tbody>
</table>

Additional information

Sometimes it might be necessary to exchange information between several callbacks that will be called one after another when a Web page is processed or form data is submitted. The user can use this mechanism to store data into the current connection context in one callback and retrieve the data from another callback of the same connection. Callbacks such as CGIs will be called in the order they are referenced by the Web page. Therefore the order of their accesses is known and can be used in dynamic memory allocation.

Examples

A sample using pseudo code is shown below.

```c
/******************************************************
* _CGI_1
* Notes
* This is the first callback accessed for the operation requested
* by the browser. This is a perfect place to allocate some memory.
*/
static void _CGI_1 (WEBS_OUTPUT *pOutput , const char *sParameters , const char *sValue)
{
    char *s;
    s = (char*)OS_malloc(13); // Allocate memory for data as
    // data has to remain valid outside
    // of this routine.
    strcpy(s, "Hello world!"); // Fill with data
    IP_WEBS_StoreUserContext(pOutput , (void*)s); // Store pointer to text for other
    // callback to access.
}

/******************************************************
* _CGI_2
* Notes
* This is the last callback accessed for the operation requested
* by the browser. This is a perfect place to free the previously
* allocated memory.
*/
static void _CGI_2 (WEBS_OUTPUT *pOutput , const char *sParameters , const char *sValue)
{
    char *s;
    s = (char*)IP_WEBS_RetrieveUserContext(pOutput); // Retrieve previously stored
    // data.
    printf("%s", s); // Output data.
    IP_WEBS_StoreUserContext(pOutput , NULL); // Invalidate user context.
    OS_free((void*)s); // Free allocated memory.
```
24.12.35 IP_WEBS_AddVFileHook()

Description

Registers a function table containing callbacks to check and serve simple virtual file content that is not further processed by the Web server.

Prototype

```c
void IP_WEBS_AddVFileHook ( WEBS_VFILE_HOOK        *  pHook ,
                          WEBS_VFILE_APPLICATION *  pVFileApp ,
                          U8                       ForceEncoding );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_VFILE_HOOK</td>
</tr>
<tr>
<td>pVFileApp</td>
<td>Pointer to a structure of WEBS_VFILE_APPLICATION</td>
</tr>
<tr>
<td>ForceEncoding</td>
<td>When set to HTTP_ENCODING_RAW chunked encoding will not be used. Necessary for some implementations such as UPnP. Further options might be added later.</td>
</tr>
</tbody>
</table>

Additional information

The function can be used to serve simple dynamically generated content for a requested file name that is simply sent back as generated by the application and is not further processed by the Web server.

Refer to Structure WEBS_VFILE_HOOK on page 685 for detailed information about the structure WEBS_VFILE_HOOK. Refer to Structure WEBS_VFILE_APPLICATION on page 684 for detailed information about the structure WEBS_VFILE_APPLICATION.

Example

```c
/* Excerpt from IP_WebserverSample_UPnP.c */

/* _UPnP_GenerateSend_upnp_xml */

Parameters

* pContextIn - Send context of the connection processed for forwarding it to the callback used for output.
* pf - Function pointer to the callback that has to be for sending the content of the VFile.
* pContextOut - Out context of the connection processed.
* pData - Pointer to the data that will be sent
* NumBytes - Number of bytes to send from pData. If NumBytes is passed as 0 the send function will run a strlen() on pData expecting a string.

Notes

* (1) The data does not need to be sent in one call of the callback routine. The data can be sent in blocks of data and will be flushed out automatically at least once returning from this routine.

*/
static void _UPnP_GenerateSend_upnp_xml(void * pContextIn, void (*pf) (void * pContextOut, const char * pData, unsigned NumBytes)) {
  char ac[128];

  pf(pContextIn, "<?xml version="1.0"?>\n" "<root xmlns="urn:schemas-upnp-org:device-1-0">\n" "<specVersion>\n" "<major>1</major>\n" "<minor>0</minor>\n"
```

```
/* Excerpt from IP_WebserverSample_UPnP.c */

// UPnP webserver VFile hook
static WEB_VFILE_HOOK _UPnP_VFileHook;

/* Excerpt from IP_WebserverSample_UPnP.c */

/*********************************************************************
*   _UPnP_CheckVFile
*
*   Check if we have content that we can deliver for the requested file using the VFile hook system.
*
*   Parameters
*      sFileName    - Name of the file that is requested
*      pIndex       - Pointer to a variable that has to be filled with the index of the entry found in case of using a filename<->content list.
*                      Alternative all comparisons can be done using the filename. In this case the index is meaningless and does not need to be returned by this routine.
*
*   Return value
*      0           - We do not have content to send for this filename, fall back to the typical methods for retrieving a file from the Web server.
*      1           - We have content that can be sent using the VFile hook system.
*/
static int _UPnP_CheckVFile ( const char * sFileName , unsigned * pIndex )  {
unsigned i ;

// Generated VFiles
if  ( strcmp ( sFileName ,  "/upnp.xml" )  ==  0 )  {
   return  1 ;
}

// Static VFiles
for  ( i =  0 ;  i <  SEGGER_COUNTOF ( _VFileList );  i ++)  {
   if  ( strcmp ( sFileName ,  _VFileList [ i]. sFileName )  ==  0 )  {
         * pIndex =  i ;
         return  1 ;
   }
}
return  0 ;
}

/*********************************************************************
*   _UPnP_SendVFile
*
*   Send the content for the requested file using the callback provided.
*
*   Parameters
*      pContextIn    - Send context of the connection processed for forwarding it to the callback used for output.
*      Index         - Index of the entry of a filename<->content list if used. Alternative all comparisons can be done using the filename. In this case the index is meaningless. If using a filename<->content list this is faster than searching again.
*      sFileName     - Name of the file that is requested. In case of working with the Index this is meaningless.
*      pf            - Function pointer to the callback that has to be for sending the content of the VFile.
*      pContextOut   - Out context of the connection processed.
*      pData         - Pointer to the data that will be sent.
/*  *  NumBytes  - Number of bytes to send from pData. If NumBytes  *  is passed as 0 the send function will run a strlen()  *  on pData expecting a string.  */
static  void  _UPnP_SendVFile ( void  *  pContextIn ,  unsigned  Index ,  const  char  *  sFileName ,  void  (* pf )  ( void  *  pContextOut ,  const  char  *  pData ,  unsigned  NumBytes ))  {
    (void)sFileName;
    // Generated VFiles
    //
    if  ( strcmp ( sFileName ,  "upnp.xml" )  ==  0 )  {
        _UPnP_GenerateSend_upnp_xml ( pContextIn ,  pf );
        return ;
    }
    // Static VFiles
    //
    pf ( pContextIn , _VFileList [ Index ]. pData , _VFileList [ Index ]. NumBytes );
}
static  WEBS_VFILE_APPLICATION _UPnP_VFileAPI =  {
    _UPnP_CheckVFile ,
    _UPnP_SendVFile
};

/* Excerpt from IP_WebserverSample_UPnP.c */

/*****************************************************************************/
/*  *  MainTask  */
/*  */
void  MainTask ( void );
void  MainTask ( void )  {
    // Activate UPnP with VFile hook for needed XML files
    IP_WEBS_AddVFileHook( & _UPnP_VFileHook , & _UPnP_VFileAPI , HTTP_ENCODING_RAW );
}
24.12.36 IP_WEBS_CompareFilenameExt()

Description
Checks if the given filename has the given extension

Prototype

```
char IP_WEBS_CompareFilenameExt(const char * sFilename,
                                const char * sExt);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sFilename</td>
<td>Null-terminated filename, such as “Index.html”</td>
</tr>
<tr>
<td>sExt</td>
<td>Null-terminated filename extension with dot, such as “.html”</td>
</tr>
</tbody>
</table>

Return value

- 0   Match.
- ≠ 0 Mismatch.

Additional information

The test is case-sensitive, meaning:

```
IP_WEBS_CompareFilenameExt("Index.html", ".html")    ---> Match
IP_WEBS_CompareFilenameExt("Index.htm", ".html")    ---> Mismatch
IP_WEBS_CompareFilenameExt("Index.HTML", ".html")   ---> Mismatch
IP_WEBS_CompareFilenameExt("Index.html", ".HTML")   ---> Mismatch
```
24.12.37  IP_WEBS_ConfigSendVFileHeader()

Description
Configures behavior of automatically sending a header containing a MIME type associated to the requested files extension based on an internal list for a requested virtual file.

Prototype

```c
void IP_WEBS_ConfigSendVFileHeader(U8 OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| OnOff     | Default: On.  
  • 0: Off, header will not be automatically generated and sent.  
  • 1: On, header will be automatically generated. |

Additional information
In case you decide not to let the Web server generate a header with the best content believed to be known you will either have to completely send a header on your own or sending a header using the function IP_WEBS_SendHeader(). Sending a header has to be done before sending any other content.
24.12.38 IP_WEBS_ConfigSendVFileHookHeader()

Description
Configures behavior of automatically sending a header containing a MIME type associated to the requested files extension based on an internal list for a requested file being served by a registered VFile hook.

Prototype

```c
void IP_WEBS_ConfigSendVFileHookHeader(U8 OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| OnOff     | Default: On.  
|           | • 0: Off, header will not be automatically generated and sent.  
|           | • 1: On, header will be automatically generated. |

Additional information
In case you decide not to let the Web server generate a header with the best content believed to be known you will either have to completely send a header on your own or sending a header using the function IP_WEBS_SendHeader(). Sending a header has to be done before sending any other content.
24.12.39  IP_WEBS_DecodeAndCopyStr()

**Description**
Checks if a string includes url encoded characters, decodes the characters and copies them into destination buffer.

**Prototype**

```c
void IP_WEBS_DecodeAndCopyStr(       char  *  pDest,
                      int     DestLen,
                        const  char  *  pSrc,
                      int     SrcLen);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDest</td>
<td>Buffer to store the decoded string.</td>
</tr>
<tr>
<td>DestLen</td>
<td>Size of the destination buffer.</td>
</tr>
<tr>
<td>pSrc</td>
<td>Source string that should be decoded.</td>
</tr>
<tr>
<td>SrcLen</td>
<td>Size of the source string.</td>
</tr>
</tbody>
</table>

**Additional information**
Destination string is 0-terminated. Source and destination buffer can be identical.

<table>
<thead>
<tr>
<th>pSrc</th>
<th>SrcLen</th>
<th>pDest</th>
<th>DestLen</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;FirstName=J%F6rg&quot;</td>
<td>16</td>
<td>&quot;FirstName=Jörg&quot;</td>
<td>15</td>
</tr>
<tr>
<td>&quot;FirstName=John&quot;</td>
<td>14</td>
<td>&quot;FirstName=John&quot;</td>
<td>15</td>
</tr>
</tbody>
</table>
24.12.40  IP_WEBS_DecodeString()

Description
Checks if a string includes url encoded characters, decodes the characters.

Prototype

```
ip int IP_WEBS_DecodeString(const char * s);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Pointer to a zero-terminated string.</td>
</tr>
</tbody>
</table>

Return value

- `< 0`  Error.
- `= 0`  String does not include url encoded characters. No change.
- `> 0`  Length of the decoded string excluding the terminating null character.
24.12.41 IP_WEBS_GetDecodedStrLen()

Description
Returns the length of a HTML encoded string when decoded excluding null character.

Prototype

\[
\text{int } \text{IP}_\text{WEBS}_\text{GetDecodedStrLen}(\text{const char } * \ s, \\
\quad \text{int } \ Len);
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(s)</td>
<td>Pointer to a string.</td>
</tr>
<tr>
<td>(\text{Len})</td>
<td>Length of the source string excluding terminating null character.</td>
</tr>
</tbody>
</table>

Return value

\(< 0\) Error.
\(> 0\) Length of decoded string excluding the terminating null character.
24.12.42  IP_WEBS_GetNumParas()

Description
Returns the number of parameters/value pairs.

Prototype

```c
int IP_WEBS_GetNumParas(const char * sParameters);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sParameters</td>
<td>Null-terminated parameter string, such as “Var1=Val1&amp;Var2=Val2”</td>
</tr>
</tbody>
</table>

Return value

= -1  No parameter/value pair / error in parameter string detected
> 0   Number of parameter/value pairs

Additional information

Parameters are separated from values by a “=“. If a string includes more as one parameter/value pair, the parameter/value pairs are separated by a “&“. For example, if the virtual file Send.cgi gets two parameters, the string should be similar to the following: ”Send.cgi?FirstName=Foo&LastName=Bar“.

sParameter is in this case FirstName=Foo&LastName=Bar. If you call IP_WEBS_GetNumParas() with this string, the return value will be 2.
24.12.43  IP_WEBS_GetParaValue()

Description
Parses a string for valid parameter/value pairs and writes results in buffer.

Prototype

```
int IP_WEBS_GetParaValue(const char * sBuffer,
                        int   ParaNum,
                        char * sPara,
                        int   ParaLenIn,
                        char * sValue,
                        int   ValueLenIn);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sBuffer</td>
<td>Zero-terminated string that should be parsed</td>
</tr>
<tr>
<td>ParaNum</td>
<td>Zero-based index of the parameter/value pairs.</td>
</tr>
<tr>
<td>sPara</td>
<td>Buffer to store the parameter name. (Optional, can be NULL.)</td>
</tr>
<tr>
<td>ParaLenIn</td>
<td>Size of the buffer to store the parameter. (0 if sPara is NULL.)</td>
</tr>
<tr>
<td>sValue</td>
<td>Buffer to store the value. (Optional, can be NULL.)</td>
</tr>
<tr>
<td>ValueLenIn</td>
<td>Size of the buffer to store the value. (0 if sValue is NULL.)</td>
</tr>
</tbody>
</table>

Return value

- 0   OK
- > 0  Error

Additional information

A valid string is in the following format:

```
<Param0>=<Value0>&<Param1>=<Value1>& ... <Paramn>=<Valuen>
```

If the parameter value string is FirstName=John&LastName=Doo and parameter 0 should be copied, sPara will be FirstName and sValue John. If parameter 1 should be copied, sPara will be LastName and sValue Doo.
24.12.44   IP_WEBS_GetParaValuePtr()

Description
Parses a string for valid parameter/value pairs and returns a pointer to the requested parameter and the length of the parameter string without termination.

Prototype

```c
int IP_WEBS_GetParaValuePtr(const char * sBuffer,
int ParaNum,
const char ** ppPara,
int * pParaLen,
const char ** ppValue,
int * pValueLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sBuffer</td>
<td>Zero-terminated parameter/value string that should be parsed.</td>
</tr>
<tr>
<td>ParaNum</td>
<td>Zero-based index of the parameter/value pairs.</td>
</tr>
<tr>
<td>ppPara</td>
<td>Pointer to the pointer locating the start of the requested parameter name. (Optional, can be NULL.)</td>
</tr>
<tr>
<td>pParaLen</td>
<td>Pointer to a buffer to store the length of the parameter name without termination. (Optional, can be NULL.)</td>
</tr>
<tr>
<td>ppValue</td>
<td>Pointer to the pointer locating the start of the requested parameter value. (Optional, can be NULL.)</td>
</tr>
<tr>
<td>pValueLen</td>
<td>Pointer to a buffer to store the length of the parameter value without termination. (Optional, can be NULL.)</td>
</tr>
</tbody>
</table>

Return value

- 0 OK
- > 0 Error

Additional information
A valid string is in the following format:

```c
<Param0>=<Value0>&<Param1>=<Value1>& ... <Paramn>=<Valuen>
```

This function can be used in case you simply want to check or use the parameters passed by the client without modifying them. Depending on your application this might save you a lot of stack that otherwise would have to be wasted for copying the same data that is already perfectly present to another location. This saves execution time as of course the data will not have to be copied.

Example

```c
/* Excerpt from IP_WebserverSample.c */
/*******************************************************************************/
*/
 static void _callback_CGI_Send(WEBS_OUTPUT * pOutput, const char * sParameters) {
     int r;
     const char * pFirstName;
     int FirstNameLen;
     const char * pLastName;
     int LastNameLen;
```
IP_WEBS_SendString(pOutput, "<HTML><HEAD><TITLE>Virtual file example</TITLE></HEAD>");
IP_WEBS_SendString(pOutput, "<style type="text/css">\nH1, H2, H3, H4 { color: white; font-family: Helvetica; }\nPRE { color: white; margin-left: 2%; font-size:150%;\nBODY{padding:0px; margin:0px; text-align:center; font-family:Verdana, Helvetica, sans-serif; background:#6699CC url(bg.png) repeat-x; font-size:11px; color:white }\nA:link { font-weight:bold; color:white; text-decoration:none; }\nA:visited { font-weight:bold; color:silver; text-decoration:none; }\nA:focus { font-weight:bold; color:white; text-decoration:underline; }\nA:hover { font-weight:bold; color:silver; text-decoration:none; }\nA:active { font-weight:bold; color:white; text-decoration:underline; }\n</style>\n";
IP_WEBS_SendString(pOutput, "<BODY><CENTER><HR><H2>Virtual file example</H2><HR></CENTER><BR><BR><BR>
\nif ( r == 0 ) {\n  IP_WEBS_SendString(pOutput, "First name: ");
  IP_WEBS_SendMem(pOutput, pFirstName, FirstNameLen);
  IP_WEBS_SendString(pOutput, "<BR>Last name: ");
  IP_WEBS_SendMem(pOutput, pLastName, LastNameLen);
} else {
  IP_WEBS_SendString(pOutput, "<BR>Error!");
}
IP_WEBS_SendString(pOutput, "<BR><BR>");
24.12.45  IP_WEBS_GetConnectInfo()

Description
Retrieves the connect info that has been passed to the Web Server process function from
the application.

Prototype

```c
void *IP_WEBS_GetConnectInfo(WEBS_OUTPUT * pOutput);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
</tbody>
</table>

Return value
Connection info passed to process function.
24.12.46  IP_WEBS_GetURI()

Description
Retrieves the requested URI up to the '?' char or the “full URI” including ‘?’ character and all characters up to the next space.

Prototype

```
char * IP_WEBS_GetURI (WEBS_OUTPUT * pOutput,
                          char GetFullURI);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
<tr>
<td>GetFullURI</td>
<td>Switch to select between URI and “full URI”. URI contains the resource address up to any delimiter such as “?”. The “full URI” contains the complete resource address accessed up to the next whitespace after the resource address including “?” and following characters. 0: URI. 1: “full URI”</td>
</tr>
</tbody>
</table>

Return value

Pointer to URI or “full URI”. NULL in case “full URI” was requested but no buffer was available to store the “full URI”.

Additional information

To support storing the “full URI” the define WEBS_URI_BUFFER_SIZE needs to be set. If it is not set or its size is too small, requesting the “full URI” will always return NULL.
24.12.47  IP_WEBS_UseRawEncoding()

**Description**

Overrrides the previously selected encoding of the Web Server to use RAW encoding. This also means closing the connection after answering the request.

**Prototype**

```c
void IP_WEBS_UseRawEncoding(WEBS_OUTPUT * pOutput);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Out context of the connection.</td>
</tr>
</tbody>
</table>
24.12.48  IP_WEBS_AUTH_DIGEST_CalcHA1()

Description
Calculates the auth digest MD5 hash for the HA1 hash value to use in the WEBS_ACCESS_CONTROL table.

Prototype

```c
void  IP_WEBS_AUTH_DIGEST_CalcHA1(const  char      *  pInput,
                                  unsigned    InputLen,
                                  char      *  pBuffer,
                                  unsigned    BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pInput</td>
<td>Input string of “User:realm:Pass”.</td>
</tr>
<tr>
<td>InputLen</td>
<td>Length of input string without termination.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to buffer that is at least 32 bytes to hold the unterminated ASCII MD5 hash.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>32 bytes or more.</td>
</tr>
</tbody>
</table>
24.12.49  IP_WEBS_AUTH_DIGEST_GetURI()

Description
Retrieves the URI sent in the client authorization.

Prototype

```c
void IP_WEBS_AUTH_DIGEST_GetURI ( WEBS_OUTPUT *  pOutput ,
                                  WEBS_AUTH_DIGEST_OUTPUT *  pDigestOutput ,
                                  char                     *  pBuffer ,
                                  unsigned                 *  pNumBytes );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>pDigestOutput</td>
<td>Auth digest context.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Where to store the URI.</td>
</tr>
<tr>
<td>pNumBytes</td>
<td><strong>in</strong> Size of buffer. <strong>out</strong> Number of characters stored.</td>
</tr>
</tbody>
</table>

Additional information
This function is only valid to be used from an auth digest callback and can be used if no new nonce is to be generated (which means the client has sent an authorization line) to retrieve this field value for a look up e.g. in a nonce cache.
24.12.50  IP_WEBS_GetProtectedPath()

**Description**
Retrieves the protected path that is tried to access by the current request.

**Prototype**

```c
char *IP_WEBS_GetProtectedPath(WEBS_OUTPUT * pOutput);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Output context</td>
</tr>
</tbody>
</table>

**Return value**
No protected path is accessed: `NULL`. Protected path is accessed : Path string.
24.12.51 IP_WEBS_UseAuthDigest()

Description
Use auth digest instead of auth basic for HTTP authentication.

Prototype

```c
void IP_WEBS_UseAuthDigest(const WEBS_AUTH_DIGEST_APP_API * pAPI);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAPI</td>
<td>Auth digest application API to use.</td>
</tr>
</tbody>
</table>

Additional information

Refer to Structure `WEBS_AUTH_DIGEST_APP_API` on page 694 for more information.
24.12.52  IP_WEBS_METHOD_AddHook()

Description

Registers a callback to serve special content upon call of a METHOD.

Prototype

```c
void IP_WEBS_METHOD_AddHook(   WEBS_METHOD_HOOK * pHook,
                                 IP_WEBS_pfMethod   pf,
                                 const char              * sURI );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_METHOD_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback function for special METHOD implementation</td>
</tr>
<tr>
<td>sURI</td>
<td>Location that will execute the registered METHOD hook instead of handling it like a typical web site.</td>
</tr>
</tbody>
</table>

Additional information

The function can be used to implement Web applications that need to make use of METHODS in a special way such as REST (REpresentational State Transfer) that uses GET and POST in a different way they are typically used by a Web server. Refer to Structure WEBS_METHOD_HOOK on page 688 for detailed information about the structure WEBS_METHOD_HOOK. Refer to Callback IP_WEBS_pfMethod on page 696 for detailed information about the callback parameters of IP_WEBS_pfMethod.

Typically one URI on the server is used to serve such a special need and this function allows redefining METHODS for a specific URI for such cases. Locations within this URI such as /URI/1 in case /URI has been defined for the hook are served by the hook as well. In case further hooks are placed inside paths of other hooks the hook with the deepest path matching the requested URI will be used.

Example

```c
/* Excerpt from IP_WebserverSample.c */
/*********************************************************************/
*/
/*   _REST_cb */
/*
*  Function description
*  Callback for demonstrational REST implementation using a METHOD
*  hook. As there is no clearly defined standard for REST this
*  implementation shall act as sample and starting point on how
*  REST support could be implemented by you.
* */
/* Parameters */
* pContext    - Context for incoming data
* pOutput     - Context for outgoing data
* sMethod     - String containing used METHOD
* sAccept     - NULL or string containing value of "Accept" field of HTTP header
* sContentType - NULL or string containing value of "Content-Type" field of
*               HTTP header
* sResource   - String containing URI that was accessed
* ContentLen  - 0 or length of data submitted by client
* */
/* Return value */
* 0            - O.K.
* Other        - Error
*/
static int _REST_cb( void *pContext,
                     WEBS_OUTPUT *pOutput,
                     const char *sMethod,
                     const char *sAccept,  
                     const char *sContentType,
```
const char *sResource,
U32 ContentLen )
{
    int Len;
    char acAccept[128];
    char acContentType[32];

    // // Strings located at sAccept and sContentType need to be copied to
    // another location before calling any other Web Server API as they
    // will be overwritten.
    // if (sAccept)
    _CopyString(acAccept, sAccept, sizeof(acAccept));
    if (sContentType)
    _CopyString(acContentType, sContentType, sizeof(acContentType));

    // // Send implementation specific header to client
    // IP_WEBS_SendHeader(pOutput, NULL, "application/REST");
    // // Output information about the METHOD used by the client
    // IP_WEBS_SendString(pOutput, "METHOD: ");
    IP_WEBS_SendString(pOutput, sMethod);
    IP_WEBS_SendString(pOutput, "\n");
    // // Output information about which URI has been accessed by the client
    // IP_WEBS_SendString(pOutput, "URI: ");
    IP_WEBS_SendString(pOutput, sResource);
    IP_WEBS_SendString(pOutput, "\n");
    // // Output information about "Accept" field given in header sent by client, if any
    // if (sAccept)
    if (sAccept)
    IP_WEBS_SendString(pOutput, "Accept: ");
    IP_WEBS_SendString(pOutput, acAccept);
    IP_WEBS_SendString(pOutput, "\n");
    // // Output information about "Content-Type" field given in header sent by
    // client, if any
    // if (sContentType)
    if (sContentType)
    IP_WEBS_SendString(pOutput, "Content-Type: ");
    IP_WEBS_SendString(pOutput, acContentType);

    // // Output content sent by client, or content previously sent by client that has
    // been saved
    if (!(_acRestContent[0] || ContentLen) && sContentType)
    IP_WEBS_SendString(pOutput, "\n");
    if (!(_acRestContent[0] || ContentLen)
    IP_WEBS_SendString(pOutput, "Content:\n");
    if (ContentLen)
    { // // Update saved content
        Len = SEGGER_MIN(sizeof(_acRestContent) - 1, ContentLen);
        IP_WEBS_METHOD_CopyData(pContext, _acRestContent, Len);
        _acRestContent[Len] = 0;
    };
    if (_acRestContent[0])
    IP_WEBS_SendString(pOutput, _acRestContent);
    return 0;
}

*******************************************************************************
*  *  MainTask
void MainTask(void);
void MainTask(void) {
  //
  // Register URI "http://<ip>/REST" for demonstrational REST implementation
  //
  IP_WEBS_METHOD_AddHook(&MethodHook, _REST_cb, "/REST");
}
24.12.53 IP_WEBS_METHOD_CopyData()

Description
This function can be called from a METHOD hook callback to copy the received amount of data as stated by the “Content-Length” field of the header.

Prototype

```
int IP_WEBS_METHOD_CopyData ( void * pContext, 
                     void * pBuffer, 
                     unsigned NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>METHOD context for incoming data.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Buffer to store data into.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes to read.</td>
</tr>
</tbody>
</table>

Return value

- < 0     Error
- = 0     Connection closed
- > 0     Number of bytes read

Additional information

The function can be used to implement Web applications that need to make use of METHODS in a special way such as REST (REpresentational State Transfer) that uses GET and POST in a different way they are typically used by a Web server. Refer to Structure WEBS_METHOD_HOOK on page 688 for detailed information about the structure WEBS_METHOD_HOOK. Refer to Callback IP_WEBS_pfMethod on page 696 for detailed information about the callback parameters of IP_WEBS_pfMethod.

Typically one URI on the server is used to serve such a special need and this function allows redefining METHODS for a specific URI for such cases. Locations within this URI such as /URI/1 in case /URI has been defined for the hook are served by the hook as well. In case further hooks are placed inside paths of other hooks the hook with the deepest path matching the requested URI will be used.
24.12.54 IP_WEBS_WEB_SOCKET_AddHook()

Description
This function registers a WebSocket hook that can be used to connect to a WebSocket implementation.

Prototype

```c
void IP_WEBS_WEB_SOCKET_AddHook( WEBS_WEB_SOCKET_HOOK * pHook,
                                 const IP_WEBS_WEB_SOCKET_API * pAPI,
                                 const char * sURI,
                                 const char * sProto);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_WEB_SOCKET_HOOK.</td>
</tr>
<tr>
<td>pAPI</td>
<td>Web Server WebSocket API layer to use.</td>
</tr>
<tr>
<td>sURI</td>
<td>Resource to register for WebSocket usage instead of handling it like a typical website.</td>
</tr>
<tr>
<td>sProto</td>
<td>WebSocket protocol name.</td>
</tr>
</tbody>
</table>

Additional information
This function is only meant to register an URI for using it with the WebSocket protocol. A WebSocket stack is required for handling the protocol itself.
24.12.55  IP_WEBS_HEADER_AddFieldHook()

**Description**

Registers a callback that will be notified if the registered header field is received.

**Prototype**

```c
void IP_WEBS_HEADER_AddFieldHook(       WEBS_OUTPUT            *  pOutput,
                                        WEBS_HEADER_FIELD_HOOK *  pHook,
                                        IP_WEBS_pfHeaderField    pf,
                                        const  char                    *  sField);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>pHook</td>
<td>Pointer to a structure of WEBS_HEADER_FIELD_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback function that gets notified if the registered header field is received.</td>
</tr>
<tr>
<td>sField</td>
<td>Header field to catch, e.g.: “Cookie: ”.</td>
</tr>
</tbody>
</table>

**Additional information**

This function can be used to notify a callback for example if an HTTP cookie is received via the header field “Cookie: ”. Multiple hooks can be registered to the same context but each header is only allowed to be registered once. Hooks need to be registered for each new request again. Use IP_WEBS_AddProgressHook() if unsure when a request begins/ends. Other callback mechanism can be used as well.

The callback `pf` can return either `WEBS_OK` to remove the current line with the header field from the input buffer or return with `WEBS_HEADER_FIELD_UNTOUCHED` if, and only if, the line has not been modified by reading it form the input buffer or something else. In case of `WEBS_HEADER_FIELD_UNTOUCHED` the line will then be processed as it would normally by the server.
24.12.56  IP_WEBS_HEADER_CopyData()

Description
Copies the requested amount of data from line with the current header field.

Prototype

```c
int IP_WEBS_HEADER_CopyData (WEBS_OUTPUT * pOutput,
                              void         * pBuffer,
                              unsigned       BufferSize,
                              unsigned     * pNumBytesLeft);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Buffer where to store data from input buffer into.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Buffer size.</td>
</tr>
<tr>
<td>pNumBytesLeft</td>
<td>Where to store the number of bytes left to read from the current line. Can be NULL.</td>
</tr>
</tbody>
</table>

Return value

- `< 0`    Error.
- `≥ 0`    Number of bytes read.

Additional information

This function can be called multiple times until `pNumBytesLeft` tells you that the end of the line has been reached.
24.12.57  IP_WEBS_HEADER_GetFindToken()

Description
Searches the current header line for a token and copies its value into a buffer.

Prototype

```c
int IP_WEBS_HEADER_GetFindToken(       WEBS_OUTPUT * pOutput,
                                       const char         * sToken,
                                       int            TokenLen,
                                       char         * pBuffer,
                                       int            BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>sToken</td>
<td>Token to find in current header line e.g. “pagecnt”.</td>
</tr>
<tr>
<td>TokenLen</td>
<td>Length of token to find without string termination.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Buffer where to store the value if the token is found. The value is not automatically string terminated. Can be NULL to check for a token and its length.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of buffer at pValBuffer.</td>
</tr>
</tbody>
</table>

Return value

- < 0  Token not found.
- ≥ 0  Token found, length of value (0 if token without value “HttpOnly;”). If pBuffer is not big enough, the copy is aborted but but the length of the value if it would fit is returned.

Additional information

This function is meant to be used from an IP_WEBS_HEADER_AddFieldHook() callback once a header field to catch has been found. This function is an alternative to using IP_WEBS_HEADER_CopyData() as it allows to copy only the token you are looking for instead of copying the whole line from the input buffer. It does not only allow to process a single token with less memory but also allows to check for tokens more easily.
24.12.58  IP_WEBS_HEADER_SetCustomFields()

Description
Sets a custom string of header fields to be included with the next header sent.

Prototype

```c
void IP_WEBS_HEADER_SetCustomFields(       
    WEBS_OUTPUT * pOutput, 
    const char * sAddFields);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>sAddFields</td>
<td>String with additional header fields. The pointer has to remain valid until the request has been completely processed (or at least the header has been sent). Use IP_WEBS_Ad-</td>
</tr>
<tr>
<td></td>
<td>dProgressHook() to get notified about the END event of the request.</td>
</tr>
</tbody>
</table>

Additional information

This function can be used to set custom header fields to be sent like a “Set-Cookie:” header field to create an HTTP cookie.

Remark on usage for cookies: Only one cookie token=value pair can be set in one “Set-Cookie” line. To add multiple token=value pairs you have to add multiple ”Set-Cookie“ lines.
24.12.59   IP_UTIL_BASE64_Decode()

Description
Performs BASE-64 decoding according to RFC3548.

Prototype

```c
int IP_UTIL_BASE64_Decode(const U8 * pSrc,
                          int   SrcLen,
                          U8   * pDest,
                          int  * pDestLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pSrc</td>
<td>Pointer to the data to encode.</td>
</tr>
<tr>
<td>SrcLen</td>
<td>Number of bytes to encode.</td>
</tr>
<tr>
<td>pDest</td>
<td>Pointer to the destination buffer.</td>
</tr>
<tr>
<td>pDestLen</td>
<td>Pointer to destination buffer size, receives the number of bytes used in destination buffer.</td>
</tr>
</tbody>
</table>

Return value

- > 0   Number of source bytes encoded, further call required.
- = 0   All bytes encoded.
- < 0   Error.

Additional information

24.12.60  IP_UTIL_BASE64_Encode()

Description
Performs BASE-64 encoding according to RFC3548.

Prototype

```c
int IP_UTIL_BASE64_Encode(const U8 * pSrc,
                          int    SrcLen,
                          U8 * pDest,
                          int * pDestLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pSrc</td>
<td>Pointer to the data to encode.</td>
</tr>
<tr>
<td>SrcLen</td>
<td>Number of bytes to encode.</td>
</tr>
<tr>
<td>pDest</td>
<td>Pointer to the destination buffer.</td>
</tr>
<tr>
<td>pDestLen</td>
<td>Pointer to destination buffer size, receives the number of bytes used in destination buffer.</td>
</tr>
</tbody>
</table>

Return value

- > 0 Number of source bytes encoded, further call required.
- = 0 All bytes encoded.
- < 0 Error.

Additional information

24.12.61  IP_UTIL_BASE64_EncodeChunk()

Description
Performs chunked BASE-64 encoding according to RFC3548.

Prototype

```c
int IP_UTIL_BASE64_EncodeChunk(       IP_UTIL_BASE64_CONTEXT * pContext,
                        const U8                     * pSrc,
                        int                       SrcLen,
                        U8                     * pDest,
                        int                     * pDestLen,
                        char                      IsLastChunk);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Context holding continue information between chunks. Needs to be initialized with zero by application.</td>
</tr>
<tr>
<td>pSrc</td>
<td>Pointer to the data to encode.</td>
</tr>
<tr>
<td>SrcLen</td>
<td>Number of bytes to encode.</td>
</tr>
<tr>
<td>pDest</td>
<td>Pointer to the destination buffer.</td>
</tr>
<tr>
<td>pDestLen</td>
<td>Pointer to destination buffer size, receives the number of bytes used in destination buffer.</td>
</tr>
</tbody>
</table>
| IsLastChunk   | Is this the last chunk of the data to encode ?
|               | • 0: Further chunks will follow, carry over less than 3 bytes from the input into the next chunk that will be encoded.
|               | • ≠ 0: Last chunk, store all bytes left even if they are not a multiple of 3. |

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>Number of source bytes encoded, further call required.</td>
</tr>
<tr>
<td>= 0</td>
<td>All bytes encoded.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Additional information

## 24.13 Data structures

<table>
<thead>
<tr>
<th>Structure / Callback</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WEBS_CGI</td>
<td>Used to store the CGI command names and the pointer to the proper callback functions.</td>
</tr>

<tr>
<td>WEBS_VFILE_APPLICATION</td>
<td>Used to check if the application can provide content for a simple VFile.</td>
</tr>
<tr>
<td>WEBS_VFILE_HOOK</td>
<td>Used to send application generated content from the application upon request of a specific file name.</td>
</tr>
<tr>
<td>WEBS_FILE_TYPE</td>
<td>Used to extend or overwrite the file extension to MIME type correlation.</td>
</tr>
<tr>
<td>WEBS_FILE_TYPE_HOOK</td>
<td>Used to extend or overwrite the file extension to MIME type correlation.</td>
</tr>
<tr>
<td>WEBS_METHOD_HOOK</td>
<td>Used to extend the usage of METHODS in the Web server for a given URI.</td>
</tr>
<tr>
<td>WEBS_PRE_CONTENT_OUTPUT_HOOK</td>
<td>Used to intercept the Web server before content is generated and sent.</td>
</tr>
<tr>
<td>WEBS_PROGRESS_HOOK</td>
<td>Used to get notified of the current progression of the requests served.</td>
</tr>
<tr>
<td>WEBS_PROGRESS_INFO</td>
<td>Used to pass information to a callback registered to be notified about the progression.</td>
</tr>
<tr>
<td>WEBS_REQUEST_NOTIFY_HOOK</td>
<td>Used to get notified of incoming requests to the Web server.</td>
</tr>
<tr>
<td>WEBS_REQUEST_NOTIFY_INFO</td>
<td>Used to pass information to a callback registered to be notified upon a request to the Web server.</td>
</tr>
<tr>
<td>WEBS_AUTH_DIGEST_APP_API</td>
<td>Used to interact with the application when Digest Authentication is used.</td>
</tr>
<tr>
<td>IP_WEBS_WEBSOCKET_API</td>
<td>Used for interaction between webserver and a WebSocket implementation.</td>
</tr>
<tr>
<td>IP_WEBS_pfMethod</td>
<td>Used to extend the usage of METHODS in the Web server for a given URI.</td>
</tr>
<tr>
<td>IP_WEBS_pfPreContentOutput</td>
<td>Called before content is generated and sent by the Web server in regular cases like VFiles and files from a filesystem.</td>
</tr>
<tr>
<td>IP_WEBS_pfRequestNotify</td>
<td>Called upon a request to the Web server.</td>
</tr>
</tbody>
</table>
24.13.1 Structure WEBS_CGI

Description
Used to store the CGI command names and the pointer to the proper callback functions.

Prototype

```c
typedef struct {
    const char * sName;
    void (*pf)(WEBS_OUTPUT * pOutput, const char * sParameters);
} WEBS_CGI;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Name of the CGI command.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to a callback function.</td>
</tr>
</tbody>
</table>

Additional information
Refer to Common Gateway Interface (CGI) on page 582 for detailed information about the use of this structure.
24.13.2 Structure WEBS_ACCESS_CONTROL

Description
Used to store information for the HTTP Basic/Digest Authentication scheme.

Prototype

```c
typedef struct {
    const char * sPath;
    const char * sRealm;
    const char * sUserPass;
    const char * sCredentialsHash;
} WEBS_ACCESS_CONTROL;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sPath</td>
<td>A string which defines the path of the resources.</td>
</tr>
<tr>
<td>sRealm</td>
<td>A string which defines the realm which requires authentication. Optional, can be NULL.</td>
</tr>
<tr>
<td>sUserPass</td>
<td>A string containing the user name[/password] combination. Basic auth: “User:Pass”. Digest auth: “User”. Optional, can be NULL.</td>
</tr>
<tr>
<td>sCredentialsHash</td>
<td>A string containing the Digest credentials hash. Basic auth: Not used. Digest auth: MD5(&quot;User:Realm:Pass&quot;). Optional, can be NULL.</td>
</tr>
</tbody>
</table>

Additional information

If sRealm is initialized with NULL, sUserPass is not interpreted by the Web server. Refer to Basic Authentication on page 592 for detailed information about the HTTP Basic Authentication scheme and Digest Authentication on page 596 about the HTTP Digest Authentication scheme.
24.13.3 Structure WEBS_APPLICATION

Description

Used to store application-specific parameters.

Prototype

typedef struct {
    const WEBS_CGI * paCGI;
    WEBS_ACCESS_CONTROL * paAccess;
    void (*pfHandleParameter)(        WEBS_OUTPUT * pOutput,
                                      const char * sPara,
                                      const char * sValue );

    const WEBS_VFILES * paVFiles;
} WEBS_APPLICATION;

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paCGI</td>
<td>Pointer to an array of structures of type WEBS_CGI.</td>
</tr>
<tr>
<td>paAccess</td>
<td>Pointer to an array of structures of type WEBS_ACCESS_CONTROL.</td>
</tr>
<tr>
<td>pfHandleParameter</td>
<td>Fallback callback in case paCGI is NULL.</td>
</tr>
<tr>
<td>paVFiles</td>
<td>Pointer to an array of structures of type WEBS_VFILES.</td>
</tr>
</tbody>
</table>
24.13.4 Structure IP_WEBS_FILE_INFO

Description
Used to store file-specific parameters.

Prototype

```c
typedef struct {
    const IP_FS_API* pFS_API; // Allows override of FS API to use for a file.
    U32 DateLastMod; // Used for "Last modified" header field
    U32 DateExp; // Used for "Expires" header field
    U8 IsVirtual;
    U8 AllowDynContent;
} IP_WEBS_FILE_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pFS_API</td>
<td>File system API override.</td>
</tr>
<tr>
<td>DateLastMod</td>
<td>The date when the file has been last modified.</td>
</tr>
<tr>
<td>DateExp</td>
<td>The date of the expiration of the validity.</td>
</tr>
<tr>
<td>IsVirtual</td>
<td>Flag to indicate if a file is virtual or not. Valid values are 0 for non-virtual, 1 for virtual files.</td>
</tr>
<tr>
<td>AllowDynContent</td>
<td>Flag to indicate if a file should be parsed for dynamic content or not. 0 means that the file should not be parsed for dynamic content, 1 means that the file should be parsed for dynamic content.</td>
</tr>
</tbody>
</table>
### 24.13.5 Structure WEBS_VFILE_APPLICATION

**Description**

Used to check if the application can provide content for a simple VFile.

**Prototype**

```c
typedef struct WEBS_VFILE_APPLICATION {
    int (*pfCheckVFile)(const char *sFileName, unsigned *pIndex);
    void (*pfSendVFile)(void *pContextIn,
                        unsigned Index,
                        const char *sFileName,
                        void (*)(void *pContextOut,
                                  const char *pData,
                                  unsigned NumBytes));
} WEBS_VFILE_APPLICATION;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfCheckVFile</td>
<td>Pointer to a callback for checking if content for a requested file name can be served.</td>
</tr>
<tr>
<td>pfSendVFile</td>
<td>Pointer to a callback for actually sending the content for the requested file name using the provided callback pf. In case NumBytes is passed with '0' the callback expects to find a string and will automatically run strlen() to find out the length of the string internally. In case NumBytes is not passed '&gt;'0' only NumBytes from the start of pData will be sent.</td>
</tr>
</tbody>
</table>
24.13.6 Structure WEBS_VFILE_HOOK

Description
Used to send application generated content from the application upon request of a specific file name.

Prototype

```
typedef struct WEBS_VFILE_HOOK {
  struct WEBS_VFILE_HOOK *pNext;
  WEBS_VFILE_APPLICATION *pVFileApp;
} WEBS_VFILE_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_VFILE_HOOK.</td>
</tr>
<tr>
<td>pVFileApp</td>
<td>Pointer to an element of type WEBS_VFILE_APPLICATION.</td>
</tr>
</tbody>
</table>

Additional information
Refer to Structure WEBS_VFILE_HOOK on page 685 for detailed information about the structure WEBS_VFILE_HOOK. Refer to Structure WEBS_VFILE_APPLICATION on page 684 for detailed information about the structure WEBS_VFILE_APPLICATION.
24.13.7 Structure WEBS_FILE_TYPE

Description
Used to extend or overwrite the file extension to MIME type correlation.

Prototype

```c
typedef struct WEBS_FILE_TYPE {
  const char *sExt;
  const char *sContent;
} WEBS_FILE_TYPE;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sExt</td>
<td>String containing the extension without leading dot.</td>
</tr>
<tr>
<td>sContent</td>
<td>String containing the MIME type associated to the extension.</td>
</tr>
</tbody>
</table>
24.13.8  Structure WEBS_FILE_TYPE_HOOK

Description

Used to extend or overwrite the file extension to MIME type correlation.

Prototype

```c
typedef struct WEBS_FILE_TYPE_HOOK {
    struct WEBS_FILE_TYPE_HOOK * pNext;
    WEBS_FILE_TYPE     FileType;
} WEBS_FILE_TYPE_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_FILE_TYPE_HOOK.</td>
</tr>
<tr>
<td>FileType</td>
<td>Element of Structure WEBS_FILE_TYPE.</td>
</tr>
</tbody>
</table>

Additional information

Refer to Structure WEBS_FILE_TYPE on page 686 for detailed information about the structure WEBS_FILE_TYPE.
### 24.13.9 Structure WEBS_METHOD_HOOK

**Description**

Used to extend the usage of METHODS in the Web server for a given URI.

**Prototype**

```c
typedef struct WEBS_METHOD_HOOK {
    struct WEBS_METHOD_HOOK *pNext;
    IP_WEBS_pfMethod pf;
    const char *sURI;
} WEBS_FILE_TYPE_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_METHOD_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to callback handling the requested method of type Callback IP_WEBS_pfMethod.</td>
</tr>
<tr>
<td>sURI</td>
<td>URI registered for METHODS callback.</td>
</tr>
</tbody>
</table>
24.13.10 Structure WEBS_PRE_CONTENT_OUTPUT_HOOK

Description
Used to intercept the Web server before content is generated and sent.

Prototype

```c
typedef struct WEBS_Pre_CONTENT_OUTPUT_HOOK {
    struct WEBS_Pre_CONTENT_OUTPUT_HOOK* pNext;
    IP_WEBS_pPreContentOutput pf;
} WEBS_Pre_CONTENT_OUTPUT_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_PRE_CON-</td>
</tr>
<tr>
<td></td>
<td>TENT_OUTPUT_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to callback of type Callback IP_WEBS_pPreContentOutput.</td>
</tr>
</tbody>
</table>
24.13.11 Structure WEBS_PROGRESS_HOOK

Description
Used to get notified of the current progression of the requests served.

Prototype

```c
typedef struct WEBS_PROGRESS_HOOK {
    struct WEBS_PROGRESS_HOOK *pNext;
    IP_WEBS_pfProgress pf;
} WEBS_PROGRESS_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_PROGRESS_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to callback handling the requested method of type Callback IP_WEBS_pfProgress.</td>
</tr>
</tbody>
</table>
24.13.12  Structure WEBS_PROGRESS_INFO

Description
Used to pass information to a callback registered to be notified about the progression.

Prototype

```
typedef struct WEBS_PROGRESS_INFO {
    WEBS_OUTPUT* pOutput;
    U8           Status;
} WEBS_PROGRESS_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>Status</td>
<td>Current progression status:</td>
</tr>
<tr>
<td></td>
<td>- WEBS_PROGRESS_STATUS_BEGIN</td>
</tr>
<tr>
<td></td>
<td>- WEBS_PROGRESS_STATUS_METHOD_URI_VER_PARSED</td>
</tr>
<tr>
<td></td>
<td>- WEBS_PROGRESS_STATUS_END</td>
</tr>
</tbody>
</table>
24.13.13 Structure WEBS_REQUEST_NOTIFY_HOOK

Description
Used to get notified of incoming requests to the Web server.

Prototype

```c
typedef struct WEBS_REQUEST_NOTIFY_HOOK {
    struct WEBS_REQUEST_NOTIFY_HOOK *pNext;
    IP_WEBS_pfRequestNotify pf;
} WEBS_REQUEST_NOTIFY_HOOK;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Pointer to the previously registered element of WEBS_REQUEST_NOTIFY_HOOK.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer to callback handling the requested method of type Callback IP_WEBS_pfRequestNotify.</td>
</tr>
</tbody>
</table>
24.13.14 Structure WEBS_REQUEST_NOTIFY_INFO

**Description**

Used to pass information to a callback registered to be notified upon a request to the Web server.

**Prototype**

```c
typedef struct WEBS_REQUEST_NOTIFY_INFO {
    const char* sUri;
    WEBS_OUTPUT* pOutput;
    U8 Method;
} WEBS_REQUEST_NOTIFY_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sUri</td>
<td>Pointer to string containing the requested location.</td>
</tr>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>Method</td>
<td>HTTP METHOD used in the request:</td>
</tr>
<tr>
<td></td>
<td>- METHOD_GET</td>
</tr>
<tr>
<td></td>
<td>- METHOD_HEAD</td>
</tr>
<tr>
<td></td>
<td>- METHOD_POST</td>
</tr>
</tbody>
</table>
24.13.15 Structure WEBS_AUTH_DIGEST_APP_API

Description
Used to interact with the application when Digest Authentication is used.

Prototype

```
typedef struct {
    void (*pfStoreNonce)(WEBS_OUTPUT* pOutput,
                        WEBS_AUTH_DIGEST_OUTPUT* pDigestOutput,
    void (*pfStore)(
        WEBS_OUTPUT* pOutput,
        WEBS_AUTH_DIGEST_OUTPUT* pDigestOutput,
        const char* pNonce,
        unsigned NonceLen),
    int GenerateNew);
} WEBS_AUTH_DIGEST_APP_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>pDigestOutput</td>
<td>Digest Authentication context.</td>
</tr>
<tr>
<td>pfStore</td>
<td>Callback executed from the pfStoreNonce callback to store a nonce known by the application.</td>
</tr>
<tr>
<td>- pOutput</td>
<td>Connection context.</td>
</tr>
<tr>
<td>- pDigestOutput</td>
<td>Digest Authentication context.</td>
</tr>
<tr>
<td>- pNonce</td>
<td>Pointer to buffer containing the nonce to store.</td>
</tr>
<tr>
<td>- NonceLen</td>
<td>Length of nonce to store without string termination.</td>
</tr>
</tbody>
</table>
| GenerateNew  | = 0: Use old nonce or lookup nonce in an user implemented nonce cache. Nonce timeouts can be implemented by simply generating anew nonce once a timeout is reached.  
|              | ≠ 0: Force generating a new nonce for a 401 response to send to the client. |
24.13.16  Structure IP_WEBS_WEBSOCKET_API

Description
Used for interaction between webserver and a WebSocket implementation.

Prototype

```c
typedef struct {
    int (*pfGenerateAcceptKey)( WEBS_OUTPUT* pOutput,
                               void* pSecWebSocketKey,
                               int SecWebSocketKeyLen,
                               void* pBuffer,
                               int BufferSize );
    void (*pfDispatchConnection)( WEBS_OUTPUT* pOutput,
                                   void* pConnection );
} IP_WEBS_WEBSOCKET_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGenerateAcceptKey</td>
<td>Callback used to generate the accept key that needs to be sent back for a WebSocket connection to be established. IP_WEBSOCKET_GenerateAcceptKey() can be used by the callback. Input/output buffer is the same. If this is not supported by your calculation callback the input buffer needs to be saved by your callback.</td>
</tr>
<tr>
<td>- pOutput</td>
<td>Webserver connection context.</td>
</tr>
<tr>
<td>- pSecWebSocketKey</td>
<td>Location of the received WebSocket key.</td>
</tr>
<tr>
<td>- SecWebSocketKeyLen</td>
<td>Length of the received key.</td>
</tr>
<tr>
<td>- pBuffer</td>
<td>Output buffer for the generated response key.</td>
</tr>
<tr>
<td>- BufferSize</td>
<td>Size of the output buffer for the response key.</td>
</tr>
<tr>
<td>pfDispatchConnection</td>
<td>Callback used to dispatch the connection handle from the webserver to another resource. Once the callback returns the transport connection (e.g. socket handle) no longer belongs to the webserver.</td>
</tr>
<tr>
<td>- pOutput</td>
<td>Webserver connection context.</td>
</tr>
<tr>
<td>- pConnection</td>
<td>Connection handle of the transport medium (e.g. socket handle).</td>
</tr>
</tbody>
</table>
24.13.17 Callback IP_WEBS_pfMethod

Description
Used to extend the usage of METHODs in the Web server for a given URI.

Prototype

```c
typedef int (*IP_WEBS_pfMethod) ( void *pContext,
                                 WEBS_OUTPUT *pOutput,
                                 const char *sMethod,
                                 const char *sAccept,
                                 const char *sContentType,
                                 const char *sResource,
                                 U32 ContentLen );
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>METHOD context for incoming data used with IP_WEBS_METHOD_* routines.</td>
</tr>
<tr>
<td>pOutput</td>
<td>Output context for IP_WEBS_* routines.</td>
</tr>
<tr>
<td>sMethod</td>
<td>String containing METHOD requested by client.</td>
</tr>
<tr>
<td>sAccept</td>
<td>String containing value of “Accept” field of header sent by client. May be NULL in case there was no such field.</td>
</tr>
<tr>
<td>sContentType</td>
<td>String containing value of “Content-Type” field of header sent by client. May be NULL in case there was no such field.</td>
</tr>
<tr>
<td>sResource</td>
<td>String containing URI that was accessed.</td>
</tr>
<tr>
<td>ContentLen</td>
<td>Length of data submitted by client that can be read. 0 in case no data was sent by client.</td>
</tr>
</tbody>
</table>

Note
Strings located at sAccept and sContentType need to be copied to another location before calling any other Web Server API as they will be overwritten.
24.13.18 Callback IP_WEBS_pfPreContentOutput

Description
Called before content is generated and sent by the Web server in regular cases like VFiles and files from a filesystem.

Prototype

```
typedef void (*IP_WEBS_pfPreContentOutput)(WEBS_OUTPUT* pOutput);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOutput</td>
<td>Output context for IP_WEBS_* routines.</td>
</tr>
</tbody>
</table>
24.13.19 Callback IP_WEBS_pfRequestNotify

Description
Called upon a request to the Web server.

Prototype

```c
typedef void (*IP_WEBS_pfRequestNotify) ( WEBS_REQUEST_NOTIFY_INFO* pInfo );
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pInfo</td>
<td>Pointer to structure containing information about the current request being handled of type Structure WEBS_REQUEST_NOTIFY_INFO.</td>
</tr>
</tbody>
</table>

Note
Data located in pInfo needs to be copied to another location if they shall be used outside of the callback as they will be overwritten.
24.14 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the Web server presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

Configuration used

```
#define  WEBS_IN_BUFFER_SIZE               256
#define  WEBS_OUT_BUFFER_SIZE              512
#define  WEBS_TEMP_BUFFER_SIZE             512
#define  WEBS_PARA_BUFFER_SIZE             256
#define  WEBS_ERR_BUFFER_SIZE              128
#define  WEBS_AUTH_BUFFER_SIZE             32
#define  WEBS_FILENAME_BUFFER_SIZE          32
#define  WEBS_UPLOAD_FILENAME_BUFFER_SIZE   64
```

24.14.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP Web server</td>
<td>approximately 7.0 kBytes</td>
</tr>
</tbody>
</table>

24.14.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP Web server</td>
<td>approximately 6.5 kBytes</td>
</tr>
</tbody>
</table>

24.14.3 RAM usage

Almost all of the RAM used by the Web server is taken from task stacks. The amount of RAM required for every child task depends on the configuration of your server. The table below shows typical RAM requirements for your task stacks.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>ParentTask</td>
<td>Listens for incoming connections.</td>
<td>approximately 1000 bytes</td>
</tr>
<tr>
<td>ChildTask</td>
<td>Handles a request.</td>
<td>approximately 3000 bytes</td>
</tr>
</tbody>
</table>

Note: The Web server requires at least 1 child task.

The approximate RAM usage for the Web server can be calculated as follows:

RAM usage = 0.1 kBytes + ParentTask + (NumberOfChildTasks * 3 kBytes)

**Example: Web server accepting only 1 connection**

RAM usage = 0.1 kBytes + 1000 + (1 * 3 kBytes)
RAM usage = 4.1 kBytes

**Example: Web server accepting up to 3 connections in parallel**

RAM usage = 0.1 kBytes + 1000 + (3 * 3 kBytes)
RAM usage = 10.1 kBytes
Chapter 25

SMTP client (Add-on)

The embOS/IP SMTP client is an optional extension to embOS/IP. The SMTP client can be used with embOS/IP or with a different TCP/IP stack. All functions that are required to add the SMTP client task to your application are described in this chapter.
25.1 embOS/IP SMTP client

The embOS/IP SMTP client is an optional extension which can be seamlessly integrated into your TCP/IP application. It combines a maximum of performance with a small memory footprint. The SMTP client allows an embedded system to send emails with dynamically generated content. The RAM usage of the SMTP client module has been kept to a minimum by smart buffer handling.

The SMTP client implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP SMTP client root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the SMTP client with embOS/IP.</td>
</tr>
<tr>
<td>.\Config\</td>
<td>Contains the SMTP client configuration file. Refer to SMTP client configuration on page 709 for detailed information.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the SMTP client sources, IP_SMTPC.c and IP_SMTPC.h.</td>
</tr>
<tr>
<td>.\Windows\SMTPC\</td>
<td>Contains the source, the project files and an executable to run embOS/IP SMTP client on a Microsoft Windows host.</td>
</tr>
</tbody>
</table>

25.2 Feature list

- Low memory footprint.
- Independent of the TCP/IP stack: any stack with sockets can be used.
- Support for attachments (multipart items).
- Supports AUTH TLS (with additional SSL/TLS stack) for secure connections.
- Independent of the SSL/TLS stack: any sockets based stack can be used.
- Example applications included.
- Project for executable on PC for Microsoft Visual Studio included.
25.3 Requirements

TCP/IP stack
The embOS/IP SMTP client requires a TCP/IP stack. It is optimized for embOS/IP, but any
RFC-compliant TCP/IP stack can be used. The shipment includes a Win32 simulation, which
uses the standard Winsock API and an implementation which uses the socket API of em-
bose/IP.

In addition to insecure connections the embOS/IP SMTP client API allows to secure the
connection by using an additional SSL/TLS stack if the server is capable of the STARTTLS
command.

Multi tasking
The SMTP client needs to run as a separate thread. Therefore, a multi tasking system is
required to use the embOS/IP SMTP client.
25.4 SMTP backgrounds

The Simple Mail Transfer Protocol is a text based communication protocol for electronic mail transmission across IP networks.

Using SMTP, an embOS/IP application can transfer mail to an SMTP servers on the same network or to SMTP servers in other networks via a relay or gateway server accessible to both networks. When the embOS/IP SMTP client has a message to transmit, it establishes a TCP connection to an SMTP server and transmits after the handshaking the message content.

The handshaking mechanism includes normally an authentication process. The RFC's define the following four different authentication schemes:

- PLAIN
- LOGIN
- CRAM-MD5
- NTLM

In the current version, the embOS/IP SMTP client supports only PLAIN and LOGIN authentication. The following listing shows a typical SMTP session:

```
S:  220 srv.sample.com ESMTP

25.5 Secure connections

Most modern mail servers support secure connections or might even refuse insecure connections at all. There are two ways of establishing secure connections with a mail server by utilizing an additional SSL/TLS stack:

- Establishing an SMTPS SSL/TLS connection on port 465 where the whole connection from the first data byte sent to the last byte is secured. This method is deprecated but still widely in use.
- Establish a regular insecure connection on port 25 and try to upgrade it to a secure connection using the STARTTLS command.

While the second method (starting insecure and trying to upgrade) might look less secure it is not. The security of this method is defined by the configured fallback mechanism used via the SecPolicy that can be found in Structure IP_SMTPC_MTA on page 721.

If the client is not allowed to use an insecure connection as fallback this method is as safe as encrypting the whole connection from start to end. An advantage of this method is that most firewalls will allow traffic on port 25 and existing firewall rules do not have to changed for secure/insecure connections.

For an example on how to use secure connections please refer to the IP_SendMail_Secure.c sample.
25.6 Attachments

Mail attachments are multipart items that are added to a mail. Multipart items in a mail are not limited to attachments only but this is the most common form they are used.

The embOS/IP SMTPC client allows to easily add attachments to a mail by providing an array of IP_SMTPC_MULTIPART_ITEM items that configure the attachments to add. For more information about the item structure please refer to Structure IP_SMTPC_MULTIPART_API on page 718.

Creating a list of attachments

Each item is sent via a callback that needs to be implemented by the application. Multiple items can share the same callback. To differentiate between two items that use the same callback a user context element can be set in the IP_SMTPC_MULTIPART_ITEM. This context can be a simple index or a pointer to more information about the item to send like a string with a path of a file to send from a file system.

The content type set for the item defines how the receiver will treat this attachment. The following is only a short excerpt of possible content types (MIME types) that can be used but. However all depend on being known by the receiver to be fully under- stood:

<table>
<thead>
<tr>
<th>File extension</th>
<th>Content type (MIME type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>.jpg</td>
<td>&quot;image/jpeg&quot;</td>
</tr>
<tr>
<td>.txt</td>
<td>&quot;text/plain&quot;</td>
</tr>
<tr>
<td>.zip</td>
<td>&quot;application/x-compressed&quot;</td>
</tr>
</tbody>
</table>

One extension might be known under multiple MIME types. The sender usually chooses the MIME type that is known to the system for this extension. Therefore an attachment might not be correctly recognized by the receiver as this type of file under all circumstances.

Adding the attachments to the mail

To actually add the items to the mail the list has to be assigned to the message to send. This is done by filling in the sBoundary, paMultipartItem and NumMultipartItems parameters of the IP_SMTPC_MESSAGE structure that defines the message to send. For more information about the structure defining a message please refer to Structure IP_SMTPC_MESSAGE on page 720.

A sample of adding two text files as attachment can be found in the IP_SendMail.c sample.
25.7  SMTP client configuration

The embOS/IP SMTP client can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define U8, which the preprocessor would replace with unsigned char.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

### 25.7.1 SMTP client compile time configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>SMTPC_WARN</td>
<td>--</td>
<td>Defines a function to output warnings. In debug configurations (DEBUG = 1) SMTPC_WARN maps to IP_Warnf_Application().</td>
</tr>
<tr>
<td>F</td>
<td>SMTPC_LOG</td>
<td>--</td>
<td>Defines a function to output logging messages. In debug configurations (DEBUG = 1) SMTPC_LOG maps to IP_Logf_Application().</td>
</tr>
<tr>
<td>N</td>
<td>SMTPC_SERVER_PORT</td>
<td>25</td>
<td>Defines the port where the SMTP server is listening.</td>
</tr>
<tr>
<td>N</td>
<td>SMTPC_IN_BUFFER_SIZE</td>
<td>256</td>
<td>Defines the size of the input buffer. The input buffer is used to store the SMTP replies of the SMTP server.</td>
</tr>
<tr>
<td>N</td>
<td>SMTPC_AUTH_USER_BUFFER_SIZE</td>
<td>48</td>
<td>Defines the size of the buffer used for the Base-64 encoded user name.</td>
</tr>
<tr>
<td>N</td>
<td>SMTPC_AUTH_PASS_BUFFER_SIZE</td>
<td>48</td>
<td>Defines the size of the buffer used for the Base-64 encoded password.</td>
</tr>
</tbody>
</table>
## 25.8 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_SMTPC_Send()</td>
<td>Sends an email to one or multiple recipients.</td>
</tr>
</tbody>
</table>
25.8.1 IP_SMTPC_Send()

Description
Sends an email to one or multiple recipients.

Prototype

```c
int IP_SMTPC_Send(const IP_SMTPC_API * pIP_API,
                   const IP_SMTPC_MAIL_ADDR * paMailAddr,
                   int NumMailAddr,
                   const IP_SMTPC_MESSAGE * pMessage,
                   const IP_SMTPC_MTA * pMTA,
                   const IP_SMTPC_APPLICATION * pApplication);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIP_API</td>
<td>Pointer to an IP_SMTPC_API structure.</td>
</tr>
<tr>
<td>paMailAddr</td>

</tr>
<tr>
<td></td>
<td>the array has to be filled with the data of the sender (FROM). The order</td>
</tr>
<tr>
<td></td>
<td>of the following data sets for recipients (TO), carbon copies (CC) and</td>
</tr>
<tr>
<td>NumMailAddr</td>
<td>blind carbon copies (BCC) is not relevant.</td>
</tr>
<tr>
<td>pMessage</td>
<td>Pointer to an array of IP_SMTPC_MESSAGE structures.</td>
</tr>
<tr>
<td>pMTA</td>
<td>Pointer to an array of IP_SMTPC_MTA structures.</td>
</tr>
<tr>
<td>pApplication</td>
<td>Pointer to an array of IP_SMTPC_APPLICATION structures.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK</td>
</tr>
<tr>
<td>1</td>

</tr>
</tbody>
</table>
25.9.1  Structure IP_SMTPC_API

Description
Structure with pointers to the required socket interface functions.

Prototype

```c
typedef struct {
    SMTPC_SOCKET (*pfConnect)(char * SrvAddr);
    void          (*pfDisconnect)(SMTPC_SOCKET Socket);
    int           (*pfSend)(const char * pData, int Len, SMTPC_SOCKET Socket);
    int           (*pfReceive)(char * pData, int Len, SMTPC_SOCKET Socket);
    int           (*pfUpgrade)(SMTPC_SOCKET hSock, const char * sServer);
    void          (*pfDowngrade)(SMTPC_SOCKET hSock);
} IP_SMTPC_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfConnect</td>
<td>Pointer to the connect function (for example, connect()).</td>
</tr>
<tr>
<td>pfDisconnect</td>
<td>Pointer to the disconnect function (for example, closesocket()).</td>
</tr>
<tr>
<td>pfSend</td>
<td>Pointer to a send function (for example, send()).</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Pointer to a receive function (for example, recv()).</td>
</tr>
<tr>
<td>pfUpgrade</td>
<td>Pointer to a callback function to upgrade an insecure connection to a</td>
</tr>
<tr>
<td></td>
<td>secure connection using an SSL/TLS stack.</td>
</tr>
<tr>
<td>pfDowngrade</td>
<td>Pointer to a callback function to downgrade a secure connection to an</td>
</tr>
<tr>
<td></td>
<td>insecure connection (after work is done) using an SSL/TLS stack.</td>
</tr>
</tbody>
</table>

Example

```c
/**********************************************************************
*  _Connect
*  Function description
*  Creates a socket and opens a TCP connection to the mail host.
*/
static SMTPC_SOCKET _Connect (char * SrvAddr) {
    long IP;
    long Sock;
    struct hostent * pHostEntry;
    struct sockaddr_in sin;
    int r;

    // Convert host into mail host
    pHostEntry = gethostbyname(SrvAddr);
    if (pHostEntry == NULL) {
        SMTPC_LOG(("gethostbyname failed: %s\r\n", SrvAddr));
        return NULL;
    }
    IP = *(unsigned *)(*pHostEntry -> h_addr_list);
    // Create socket and connect to mail server
    Sock = socket(AF_INET, SOCK_STREAM, 0);
    if(Sock == -1) {
        SMTPC_LOG(("Could not create socket!");
        return NULL;
    }
    if (connect(Sock, (struct sockaddr *)&sin, sizeof(sin)) < 0) {
        SMTPC_LOG(("Connect failed!");
        return NULL;
    }
    return Sock;
}
```
IP_MEMSET(&sin, 0, sizeof(sin));

sin.sin_family = AF_INET;

sin.sin_port = htons(SERVER_PORT);

sin.sin_addr.s_addr = IP;

r = connect(Sock, (struct sockaddr *)&sin, sizeof(sin));

if(r == SOCKET_ERROR) {
    SMTPC_LOG(("\nSocket error :"));
    return NULL;
}

SMTPC_LOG(("APP: Connected.\r\n"));

return (SMTPC_SOCKET) Sock;

} /* ***********************************************************/

/* _Disconnect */

*/

static void _Disconnect(SMTPC_SOCKET Socket) {
    closesocket((long)Socket);
}

} /* ***********************************************************/

/* _Send */

*/

static int _Send(const char * buf, int len, void * pConnectionInfo) {
    return send((long)pConnectionInfo, buf, len, 0);
}

} /* ***********************************************************/

/* _Recv */

*/

static int _Recv(char * buf, int len, void * pConnectionInfo) {
    return recv((long)pConnectionInfo, buf, len, 0);
}

static const IP_SMTPC_API _IP_Api = {
    _Connect,
    _Disconnect,
    _Send,
    _Recv
};
25.9.2 Structure IP_SMTPC_APPLICATION

Description
Structure with pointers to application related functions.

Prototype

typedef struct {
    U32 (*pfGetTimeDate) (void);
    int (*pfCallback)(int Stat, void *);
    const char * sDomain;  // email domain
    const char * sTimezone; // Time zone.
} IP_SMTPC_APPLICATION;

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGetTimeDate</td>
<td>Pointer to the function which returns the current system time. Used to set the correct date and time of the email.</td>
</tr>
<tr>
<td>pfCallback</td>
<td>Pointer to status callback function. Can be NULL.</td>
</tr>
<tr>
<td>sDomain</td>
<td>Domain name. For example, sample.com. According to RFC 821 the maximum total length of a domain name or number is 64 characters.</td>
</tr>
<tr>
<td>sTimezone</td>
<td>Time zone. The zone specifies the offset from Coordinated Universal Time (UTC). Offset from UTC is passed as string: “+0100”. Can be NULL.</td>
</tr>
</tbody>
</table>

Example

*****************************************************************************
*  _GetTimeDate
*/
static U32 _GetTimeDate(void) {
    U32 r;
    U16 Sec, Min, Hour;
    U16 Day, Month, Year;

    Sec   =  0;  // 0 based. Valid range: 0..59
    Min   =  0;  // 0 based. Valid range: 0..59
    Hour  =  0;  // 0 based. Valid range: 0..23
    Day   =  1;  // 1 based. Means that 1 is 1.
    Month =  1;  // 1 based. Means that January is 1. Valid range is 1..12.
    r   =  Sec /  2  +  (Min <<  5 )  +  (Hour  <<  11 );
    r  |=  ( U32 )( Day + ( Month <<  5 )  +  (Year  <<  9 ))  <<  16 ;
    return  r ;
}
*****************************************************************************

*****************************************************************************
*  _Application
*/
static const SMTPC_APPLICATION _Application = {
    _GetTimeDate,
    NULL,
    "sample.com",  // Your domain.
    NULL
};
25.9.3 Structure IP_SMTPC_MAIL_ADDR

Description
Structure to store an email address.

Prototype

```c
typedef struct {
    const char * sName;
    const char * sAddr;
    int Type;
} IP_SMTPC_MAIL_ADDR;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Name of the recipient (for example, “Foo Bar”). Can be NULL.</td>
</tr>
<tr>
<td>sAddr</td>
<td>email address of the recipient (for example, “<a href="mailto:foo@bar.com">foo@bar.com</a>”).</td>
</tr>
<tr>
<td>Type</td>
<td>Type of the email address.</td>
</tr>
</tbody>
</table>

Valid values for parameter Type

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMTPC_RECV_TYPE_FROM</td>
<td>email address of the sender (FROM).</td>
</tr>
<tr>
<td>SMTPC_RECV_TYPE_TO</td>
<td>email address of the recipient (TO).</td>
</tr>
<tr>
<td>SMTPC_RECV_TYPE_CC</td>
<td>email address of a recipient which should get a carbon copy (CC) of the email.</td>
</tr>
<tr>
<td>SMTPC_RECV_TYPE_BC</td>
<td>email address of a recipient which should get a blind carbon copy (BCC) of the email.</td>
</tr>
</tbody>
</table>

Additional information

The structure is used to store the data sets of the sender and all recipients. IP_SMTPC_Send() gets a pointer to an array of IP_SMTPC_MAIL_ADDR structures as parameter. The first element of these array has to be filled with the data of the sender (FROM). The order of the following data sets for Recipients (TO), Carbon Copies (CC) and Blind Carbon Copies (BCC) is not relevant. For detailed information about IP_SMTPC_Send() refer to IP_SMTPC_Send on page 711.

The sName could also be a UTF-8 encoded string. For example, to send “Лев Толстой” define sName as

```
"xD0\x9B\xD0\xBB\xCD0\xCD2\xCD0\xCD0\xCD0\xCD0\xCD0\xCD0\xCD0\xCD0\xCD1\xCD1\xCD1\xCD1\xCD2\xCD0\xCD0\xCD8"
```

For more details on UTF-8 encoding refer for example to https://en.wikipedia.org/wiki/Utf8.

Example

```c
/****************************************************************************
*  
*  Mailer
*/
static void _Mailer(void) {
    SMTPC_MAIL_ADDR MailAddr[4];
    SMTPC_MTA Mta;
```
SMTPC_MESSAGE Message;
IP_MEMSET(&MailAddr, 0, sizeof(MailAddr));

// Sender
//
MailAddr[0].sName  = 0; // for example, "Your name";
MailAddr[0].sAddr  = 0; // for example, "user@foobar.com";
MailAddr[0].Type  = SMTPC_REC_TYPE_FROM;

// Recipient(s)
//
MailAddr[1].sName  = 0; // "Recipient";
MailAddr[1].sAddr  = 0; // "recipient@foobar.com";
MailAddr[1].Type  = SMTPC_REC_TYPE_TO;
MailAddr[2].sName  = 0; // "CC Recp 1";
MailAddr[2].sAddr  = 0; // "cc1@foobar.com";
MailAddr[2].Type  = SMTPC_REC_TYPE_CC;
MailAddr[3].sName  = 0; // "BCC Recp 1";
MailAddr[3].sAddr  = 0; // "bcc1@foobar.com";
MailAddr[3].Type  = SMTPC_REC_TYPE_BCC;

// Message
//
Message.sSubject = "SMTP message sent via embOS/IP SMTP client";
Message.sBody    = "embOS/IP SMTP client - www.segger.com";

// Fill mail transfer agent structure
//
Mta.sServer  = 0; // for example, "mail.foobar.com";
Mta.sUser    = 0; // for example, "user@foobar.com";
Mta.sPass    = 0; // for example, "password";

// Check if sample is configured!
//
if(Mta.sServer == 0) {
    SMTPC_WARN(("You have to enter valid SMTP server, sender and recipient(s).\r\n"));
    while(1);
}

// Wait until link is up. This can take 2-3 seconds if PHY has been reset.
//
while (IP_IFaceIsReady() == 0) {
    OS_Delay(100);
}
SMTPC_Send(_IP_Api, &MailAddr[0], 4, &Message, &Mta, &_Application);
while(1);
25.9.4 Structure IP_SMTPC_MULTIPART_API

**Description**
Structure containing functions for sending multipart content (attachments).

**Prototype**

```c
typedef struct {
    void (*pfSend)(IP_SMTPC_CONTEXT* pContext,
                   const char* pData,
                   unsigned NumBytes);
} IP_SMTPC_MULTIPART_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfSend</td>
<td>Callback for sending multipart content in chunks.</td>
</tr>
<tr>
<td>- pContext</td>
<td>SMTPc context.</td>
</tr>
<tr>
<td>- pData</td>
<td>Data to send.</td>
</tr>
<tr>
<td>- NumBytes</td>
<td>Amount of data to send.</td>
</tr>
</tbody>
</table>
25.9.5 Structure IP_SMTPC_MULTIPART_ITEM

Description
Structure to store multipart items to be added to the mail.

Prototype

```c
typedef struct IP_SMTPC_MULTIPART_ITEM_STRUCT IP_SMTPC_MULTIPART_ITEM;
struct IP_SMTPC_MULTIPART_ITEM_STRUCT {
    const char* sFilename;
    const void* pUserContext;
    const char* sContentType;
    void (*pfSendItem)(IP_SMTPC_CONTEXT* pContext,
                       const IP_SMTPC_MULTIPART_ITEM* pItem,
                       const IP_SMTPC_MULTIPART_API* pAPI);
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sFilename</td>
<td>Filename suggested to client in case the multipart item is an attachment.</td>
</tr>
<tr>
<td>pUserContext</td>
<td>User context passed to <code>pfSendItem</code> callback. Can be used to pass a file path or other application information to the callback.</td>
</tr>
<tr>
<td>sContentType</td>
<td>Value for the &quot;Content-Type: &quot; field of the multipart item. Examples for a text file attachment are: &quot;text/plain&quot; or &quot;text/plain; name=Test.txt&quot;.</td>
</tr>
<tr>
<td>pfSendItem</td>
<td>Callback for sending the content of a multipart item without having to know its length upfront.</td>
</tr>
<tr>
<td>- pContext</td>
<td>SMTPc context.</td>
</tr>
<tr>
<td>- pItem</td>
<td>Item to send.</td>
</tr>
<tr>
<td>pAPI</td>
<td>API for sending data in chunks.</td>
</tr>
</tbody>
</table>
### 25.9.6 Structure IP_SMTPC_MESSAGE

**Description**

Structure to store the subject and the text and attachments of the email.

**Prototype**

```c
typedef struct {
    const char* sSubject;
    const char* sBody;
    const char* sBoundary;
    const IP_SMTPC_MULTIPART_ITEM* paMultipartItem;
    unsigned NumMultipartItems;
} IP_SMTPC_MESSAGE;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sSubject</td>
<td>Subject of the message to send. Could be UTF-8 encoded string.</td>
</tr>
<tr>
<td>sBody</td>
<td>Content of the message to send. Could be UTF-8 encoded string.</td>
</tr>
<tr>
<td>sBoundary</td>
<td>Boundary to use for multipart encoding (e.g. when using attachments). Can be NULL if (NumMultipartItems = 0).</td>
</tr>
<tr>
<td>paMultipartItem</td>
<td>Pointer to list of items (attachments) to multipart encode with the message. Can be NULL if (NumMultipartItems = 0).</td>
</tr>
<tr>
<td>NumMultipartItems</td>
<td>Number of multipart items that can be found at paMultipartItem.</td>
</tr>
</tbody>
</table>
25.9.7  Structure IP_SMTPC_MTA

Description
Structure to store the server address and the login information.

Prototype

```c
typedef struct {
  const char * sServer;
  const char * sUser;
  const char * sPass;
  US     SecPolicy;
} IP_SMTPC_MTA;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sServer</td>
<td>Server address (for example, “mail.foobar.com”).</td>
</tr>
<tr>
<td>sUser</td>
<td>Account user name (for example, “<a href="mailto:foo@bar.com">foo@bar.com</a>”). Can be NULL.</td>
</tr>
<tr>
<td>sPass</td>
<td>Account password (for example, “password”). Can be NULL.</td>
</tr>
<tr>
<td>SecPolicy</td>
<td>Security policy to use:</td>
</tr>
<tr>
<td></td>
<td>- SMTPC_SEC_POLICY_ALLOW_INSECURE (default)</td>
</tr>
<tr>
<td></td>
<td>- SMTPC_SEC_POLICY_SECURE_ONLY</td>
</tr>
</tbody>
</table>

Additional information

The parameters `sUser` and `sPass` have to be NULL if no authentication is used by the server. If `sUser` is set in the application code, the client tries to use authentication. This means that the client sends the `AUTH LOGIN` or `AUTH PLAIN` command to the server. If the server does not support authentication, he will return an error code and the client closes the session.

The parameter `SecPolicy` defines the fallback behavior in case secure connections are supported by using an additional SSL/TLS stack and providing callbacks for the function pointers for `pfUpgrade` and `pfDowngrade` in the `Structure IP_SMTPC_API` on page 713.

`SMTPC_SEC_POLICY_ALLOW_INSECURE` (default) will allow a fallback to an insecure connection to be used in case no SSL/TLS stack is available or the server does not offer the `AUTH TLS` extension.

If a secure connection is possible as the server offers the `AUTH TLS` connection a secure connection will be established.

`SMTPC_SEC_POLICY_SECURE_ONLY` forces the SMTP client to insist on a secure connection and will refuse to proceed using an insecure connection.
25.10 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the SMTP client presented in the tables below have been measured on a Cortex-M4 system. Details about the further configuration can be found in the sections of the specific example.

Configuration used

```
#define SMTPC_OUT_BUFFER_SIZE 256
#define SMTPC_IN_BUFFER_SIZE 256
#define SMTPC_AUTH_USER_BUFFER_SIZE 48
#define SMTPC_AUTH_PASS_BUFFER_SIZE 48
```

25.10.1 ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V3.10e, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP SMTP client</td>
<td>approximately 2.7 kBytes</td>
</tr>
</tbody>
</table>

25.10.2 RAM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP SMTP client buffers w/o task stack</td>
<td>approximately 600 Bytes</td>
</tr>
</tbody>
</table>

The RAM requirement for the work buffers on the task stack is approximately 600 bytes for the mentioned configuration. Only the bigger buffer size of SMTPC_AUTH_USER_BUFFER_SIZE or SMTPC_AUTH_PASS_BUFFER_SIZE is used for a single buffer.
Chapter 26

FTP server (Add-on)

The embOS/IP FTP server is an optional extension to the TCP/IP stack. The FTP server can be used with embOS/IP or with a different TCP/IP stack. All functions which are required to add a FTP server task to your application are described in this chapter.
26.1 embOS/IP FTP server

The embOS/IP FTP server is an optional extension which adds the FTP protocol to the stack. FTP stands for File Transfer Protocol. It is the basic mechanism for moving files between machines over TCP/IP based networks such as the Internet. FTP is a client/server protocol, meaning that one machine, the client, initiates a file transfer by contacting another machine, the server and making requests. The server must be operating before the client initiates his requests. Generally a client communicates with one server at a time, while most servers are designed to work with multiple simultaneous clients.

The FTP server implements the relevant parts of the following RFCs.

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RFC 959]</td>
<td>FTP - File Transfer Protocol</td>
</tr>
</tbody>
</table>

The following table shows the contents of the embOS/IP FTP server root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the FTP server with embOS/IP.</td>
</tr>
<tr>
<td>.\Config\</td>
<td>Contains the FTP server configuration file.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the FTP server sources.</td>
</tr>
<tr>
<td>.\IP\FS\</td>
<td>Contains the sources for the file system abstraction layer and the read-only file system. Refer to File system abstraction layer on page 1206 for detailed information.</td>
</tr>
<tr>
<td>.\Windows\FTPserver\</td>
<td>Contains the source, the project files and an executable to run embOS/IP FTP server on a Microsoft Windows host.</td>
</tr>
</tbody>
</table>
26.2 Feature list

- Low memory footprint.
- Multiple connections supported.
- Independent of the file system: Any file system can be used.
- Independent of the TCP/IP stack: Any stack with sockets can be used.
- Demo application included.
- Project for executable on PC for Microsoft Visual Studio included.
26.3 Requirements

TCP/IP stack

The embOS/IP FTP server requires a TCP/IP stack. It is optimized for embOS/IP, but any RFC-compliant TCP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and two implementations which use the socket API of embOS/IP (with or without TLS secured connection).

Multi tasking

The FTP server needs to run as a separate thread. Therefore, a multi tasking system is required to use the embOS/IP FTP server.
26.4 FTP basics

The File Transfer Protocol (FTP) is an application layer protocol. FTP is an unusual service in that it utilizes two ports, a ‘Data’ port and a ‘CMD’ (command) port. Traditionally these are port 21 for the command port and port 20 for the data port. FTP can be used in two modes, active and passive. Depending on the mode, the data port is not always on port 20.

When an FTP client contacts a server, a TCP connection is established between the two machines. The server does a passive open (a socket is listen) when it begins operation; thereafter clients can connect with the server via active opens. This TCP connection persists for as long as the client maintains a session with the server, (usually determined by a human user) and is used to convey commands from the client to the server, and the server replies back to the client. This connection is referred to as the FTP command connection.

The FTP commands from the client to the server consist of short sets of ASCII characters, followed by optional command parameters. For example, the FTP command to display the current working directory is `PWD` (Print Working Directory). All commands are terminated by a carriage return-linefeed sequence (CRLF) (ASCII 10,13; or Ctrl-J, Ctrl-M). The servers replies consist of a 3 digit code (in ASCII) followed by some explanatory text. Generally codes in the 200s are success and 500s are failures. See the RFC for a complete guide to reply codes. Most FTP clients support a verbose mode which will allow the user to see these codes as commands progress.

If the FTP command requires the server to move a large piece of data (like a file), a second TCP connection is required to do this. This is referred to as the FTP data connection (as opposed to the aforementioned command connection). In active mode the data connection is opened by the server back to a listening client. In passive mode the client opens also the data connection. The data connection persists only for transporting the required data. It is closed as soon as all the data has been sent.

FTP security could be guarantied by a secured connection (TLS). Server could behave as implicit server: the connection is secured from the start (generally port 990 is used). Or it could behave as an implicit server: the connection is started normally (generally port 21 is used) and updated through the AUTH command.
26.4.1 Active mode FTP

In active mode FTP the client connects from a random unprivileged port P (P > 1023) to the FTP server’s command port, port 21. Then, the client starts listening to port P+1 and sends the FTP command PORT P+1 to the FTP server. The server will then connect back to the client’s specified data port from its local data port, which is port 20.
26.4.2 Passive mode FTP

In passive mode FTP the client connects from a random unprivileged port $P$ ($P > 1023$) to the FTP server’s command port, port 21. In opposite to an active mode FTP connection where the client opens a passive port for data transmission and waits for the connection from server-side, the client sends in passive mode the “PASV” command to the server and expects an answer with the information on which port the server is listening for the data connection.

After receiving this information, the client connects to the specified data port of the server from its local data port.
26.4.3 FTP reply codes

Every FTP command is answered by one or more reply codes defined in [RFC 959]. A reply is an acknowledgment (positive or negative) sent from server to user via the control connection in response to FTP commands. The general form of a reply is a 3-digit completion code (including error codes) followed by Space <SP>, followed by one line of text and terminated by carriage return line feed <CRLF>. The codes are for use by programs and the text is usually intended for human users.

The first digit of the reply code defines the class of response. There are 5 values for the first digit:

- 1yz: Positive preliminary reply
- 2yz: Positive completion reply
- 3yz: Positive intermediate reply
- 4yz: Transient negative Completion reply
- 5yz: Permanent negative Completion reply

The second digit of the reply code defines the group of the response.

- x0z: Syntax - Syntax errors, syntactically correct commands that don’t fit any functional category, unimplemented or superfluous commands.
- x1z: Information - These are replies to requests for information, such as status or help.
- x2z: Connections - Replies referring to the control and data connections.
- x3z: Authentication and accounting - Replies for the login process and accounting procedures.
- x4z: Unspecified as yet.
- x5z: File system - These replies indicate the status of the Server file system vis-a-vis the requested transfer or other file system action.

The third digit gives a finer gradation of meaning in each of the function categories, specified by the second digit.
### 26.4.4 Supported FTP commands

embOS/IP FTP server supports a subset of the defined FTP commands. Refer to [RFC 959](https://tools.ietf.org/html/rfc959) for a complete detailed description of the FTP commands. The following FTP commands are implemented:

<table>
<thead>
<tr>
<th>FTP commands</th>
<th>Description</th>
</tr>

</table>
CHAPTER 26  Using the FTP server sample

26.5 Using the FTP server sample

Ready to use examples for Microsoft Windows and embOS/IP are supplied. If you use another TCP/IP stack the sample OS_IP_FTPServer.c has to be adapted. The sample application opens a port which listens on port 21 until an incoming connection is detected. If a connection has been established IP_FTPS_Process() handles the client request in an extra task, so that the server is further listening on port 21. The example application requires a file system to make data files available. Refer to File system abstraction layer on page 1206 for detailed information.

26.5.1 Using the FTP server Windows sample

If you have MS Visual C++ 6.00 or any later version available, you will be able to work with a Windows sample project using embOS/IP FTP server. If you do not have the Microsoft compiler, an precompiled executable of the FTP server is also supplied. The base directory of the Windows sample application is C:\FTP\.

Building the FTP server sample program

Open the workspace Start_FTPServer.dsw with MS Visual Studio (for example, double-clicking it). There is no further configuration necessary. You should be able to build the application without any error or warning message.

The server uses the IP address of the host PC on which it runs. Open a FTP client and connect by entering the IP address of the host (127.0.0.1) to connect to the FTP server. The server accepts anonymous logins. You can also login with the user name “Admin” and the password “Secret”.

26.5.2 Running the FTP server example on target hardware

The embOS/IP FTP server sample application should always be the first step to check the proper function of the FTP server with your target hardware.

Add all source files located in the following directories (and their subdirectories) to your project and update the include path:

- Application
- Config
- Inc
- IP
- IP\IP_FS\[NameOfUsedFileSystem]

It is recommended that you keep the provided folder structure.

The sample application can be used on the most targets without the need for changing any of the configuration flags. The server processes two connections using the default configuration.

Note: Two connections mean that the target can handle up one target. A target requires always two connection, one for the command transfer and one for the data transfers. Every connection is handled in an separate task. Therefore, the FTP server uses up to three tasks in the default configuration. One task which listens on port 21 and accepts connections and two tasks to process the accepted connection. To modify the number of connections only the macro MAX_CONNECTIONS has to be modified.
26.6 Access control

The embOS/IP FTP server supports a fine-grained access permission scheme. Access permissions can be defined on user-basis for every directory and every file. The access permission of a directory or a file is a combination of the following attributes: visible, readable and writable. To control the access permission four callback functions have been implemented in the user application. The callback functions are defined in the structure `FTPS_ACCESSCONTROL`. For detailed information about these structure, refer to Structure `FTPS_ACCESSCONTROL` on page 755.

26.6.1 pfFindUser()

Description

Callback function which checks if the user is valid.

Prototype

```c
int (*pfFindUser) ( const char * sUser );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sUser</td>
<td>User name.</td>
</tr>
</tbody>
</table>

Return value

- 0 - UserID invalid or unknown
- > 0 - UserID, no password required
- < 0 - UserID, password required

Example

```c
enum {
    USER_ID_ANONYMOUS = 1,
    USER_ID_ADMIN
};

/*********************************************************************
*       _FindUser
*       Callback function for user management.
*       Checks if user name is valid.
* 
* Return value
*  0  UserID invalid or unknown
*  > 0  UserID, no password required
*  < 0  - UserID, password required
*/
static int _FindUser ( const char * sUser ) {
    if ( strcmp ( sUser , "Admin" ) == 0 ) {
        return - USER_ID_ADMIN;
    }
    if ( strcmp ( sUser , "anonymous" ) == 0 ) {
        return USER_ID_ANONYMOUS;
    }
    return 0;
}
```
26.6.2 pfCheckPass()

Description
Callback function which checks if the password is valid.

Prototype

```c
int (*pfCheckPass) ( int UserId,
                     const char * sPass );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserId</td>
<td>Id number</td>
</tr>
<tr>
<td>Pass</td>
<td>Password string.</td>
</tr>
</tbody>
</table>

Return value

= 0 - UserID known, password valid.
= 1 - UserID unknown or password invalid

Example

```c
enum {
    USER_ID_ANONYMOUS = 1,
    USER_ID_ADMIN
};

/*********************************************************************
* _CheckPass
* Function description
* Callback function for user management.
* Checks user password.
* Return value
* 0 UserID know, password valid
* 1 UserID unknown or password invalid
*/
static int _CheckPass ( int UserId, const char * sPass ) {
    if ((UserId == USER_ID_ADMIN) && (strcmp(sPass, "Secret") == 0)) {
        return 0;
    } else {
        return 1;
    }
}
```
26.6.3 pfGetDirInfo()

Description
Callback function which checks the permissions of the connected user for every directory.

Prototype

```c
int (*pfGetDirInfo)(
    int UserId,
    const char * sDirIn,
    char * pDirOut,
    int SizeOfDirOut);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserId</td>
<td>Id number</td>
</tr>
<tr>
<td>sDirIn</td>
<td>Directory to check permission for</td>
</tr>
<tr>
<td>pDirOut</td>
<td>Directory that can be accessed</td>
</tr>
<tr>
<td>SizeOfDirOut</td>
<td>Size of buffer addressed by pDirOut</td>
</tr>
</tbody>
</table>

Return value

Returns a combination of the following:
- IP_FTPS_PERM_VISIBLE Directory is visible as a directory entry.
- IP_FTPS_PERM_READ Directory can be read/entered.
- IP_FTPS_PERM_WRITE Directory can be written to.

Example

```c
/* Excerpt from IP_FTPServer.h */
#define IP_FTPS_PERM_VISIBLE (1 << 0)
#define IP_FTPS_PERM_READ (1 << 1)
#define IP_FTPS_PERM_WRITE (1 << 2)

/* Excerpt from OS_IP_FTPServer.c */
/***************************************************************************/
/* 
*       _GetDirInfo 
* 
*  Function description 
*    Callback function for permission management.
*    Checks directory permissions.
* 
*  Return value 
*    Returns a combination of the following:
*    IP_FTPS_PERM_VISIBLE    - Directory is visible as a directory entry
*    IP_FTPS_PERM_READ       - Directory can be read/entered
*    IP_FTPS_PERM_WRITE      - Directory can be written to
* 
*  Parameters 
*    UserId        - User ID returned by _FindUser()
*    sDirIn        - Full directory path and with trailing slash
*    sDirOut       - Reserved for future use
*    DirOutSize    - Reserved for future use
* 
*  Notes 
*    In this sample configuration anonymous user is allowed to do anything.
*    Samples for folder permissions show how to set permissions for different
*    folders and users. The sample configures permissions for the following
*    directories:
*    - /READONLY/: This directory is read only and can not be written to.
*    - /VISIBLE/: This directory is visible from the folder it is located in
*      but can not be accessed.
*    - /ADMIN/: This directory can only be accessed by the user *Admin*.
* 
* static int _GetDirInfo(int UserId, const char* sDirIn, char* sDirOut, int DirOutSize) { 
```
int Perm;

(void)sDirOut;
(void)DirOutSize;

Perm = IP_FTPS_PERM_VISIBLE | IP_FTPS_PERM_READ | IP_FTPS_PERM_WRITE;

if (strcmp(sDirIn, "/READONLY") == 0) {
    Perm = IP_FTPS_PERM_VISIBLE | IP_FTPS_PERM_READ;
}
if (strcmp(sDirIn, "/VISIBLE") == 0) {
    Perm = IP_FTPS_PERM_VISIBLE;
}
if (strcmp(sDirIn, "/ADMIN") == 0) {
    if (UserId != USER_ID_ADMIN) {
        return 0;  // Only Admin is allowed for this directory
    }
}
return Perm;
26.6.4 pfGetFileInfo()

Description
Callback function which checks the permissions of the connected user for every file.

Prototype

```c
int (*pfGetFileInfo) ( int UserId,
const char * sFileIn,
char * pFileOut,
int SizeOfFileOut );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UserId</td>
<td>Id number</td>
</tr>
<tr>
<td>sFileIn</td>
<td>File to check permission for</td>
</tr>
<tr>
<td>pFileOut</td>
<td>File that can be accessed</td>
</tr>
<tr>
<td>SizeOfFileOut</td>
<td>Size of buffer addressed by pFileOut</td>
</tr>
</tbody>
</table>

Return value

Returns a combination of the following:
- `IP_FTPS_PERM_VISIBLE` File is visible as a file entry.
- `IP_FTPS_PERM_READ` File can be read.
- `IP_FTPS_PERM_WRITE` File can be written to.

Additional information

Providing a function for file permissions is optional. If using permissions on directory level is sufficient for your needs pfGetFileInfo may be declared NULL in the `FTPS_ACCESS_CONTROL` function table.

Example

```c
/* Excerpt from IP_FTPS_PERM_VISIBLE (1 << 0)
#define IP_FTPS_PERM_READ   (1 << 1)
#define IP_FTPS_PERM_WRITE  (1 << 2)

/* Excerpt from OS_IP_FTPS_PERM_VISIBLE */
/**************************************************************************/
**       _GetFileInfo
**  Function description
**    Callback function for permission management.
**    Checks file permissions.
**  Return value
**    Returns a combination of the following:
**    IP_FTPS_PERM_VISIBLE   - File is visible as a file entry
**    IP_FTPS_PERM_READ     - File can be read
**    IP_FTPS_PERM_WRITE    - File can be written to
**  Parameters
**    UserId        - User ID returned by _FindUser()
**    sFileIn       - Full path to the file
**    sFileOut      - Reserved for future use
**    FileOutSize   - Reserved for future use
**  Notes
**    In this sample configuration all file accesses are allowed. File
**    permissions are checked against directory permissions. Therefore it
**    is not necessary to limit permissions on files that reside in a
```
* directory that already limits access.
* Setting permissions works the same as for _GetDirInfo() .
*/
static int _GetFileInfo(int UserId, const char * sFileIn, char * sFileOut, int FileOutSize) {
    int Perm;
    (void)UserId;
    (void)sFileIn;
    (void)sFileOut;
    (void)FileOutSize;

    Perm = IP_FTPS_PERM_VISIBLE | IP_FTPS_PERM_READ | IP_FTPS_PERM_WRITE;
    return Perm;
}
26.7 Configuration

The embOS/IP FTP server can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define \texttt{U8}, which the preprocessor would replace with \texttt{unsigned char}.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

### 26.7.1 FTP server compile time configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>FTPS_WARN</td>
<td>--</td>
<td>Defines a function to output warnings. In debug configurations (\texttt{DEBUG = 1}) FTPS_WARN maps to IP_Warnf_Application().</td>
</tr>
<tr>
<td>F</td>
<td>FTPS_LOG</td>
<td>--</td>
<td>Defines a function to output logging messages. In debug configurations (\texttt{DEBUG = 1}) FTPS_LOG maps to IP_Logf_Application().</td>
</tr>
<tr>
<td>N</td>
<td>FTPS_BUFFER_SIZE</td>
<td>512</td>
<td>Defines the size of the send and receive buffer of the FTP server.</td>
</tr>
<tr>
<td>N</td>
<td>FTPS_MAX_PATH</td>
<td>128</td>
<td>Defines the maximum length of the buffer used for the path string.</td>
</tr>
<tr>
<td>N</td>
<td>FTPS_MAX_PATH_DIR</td>
<td>128</td>
<td>Defines the maximum length of the buffer used for the directory string.</td>
</tr>
<tr>
<td>N</td>
<td>FTPS_MAX_FILE_NAME</td>
<td>13</td>
<td>Defines the maximum length of the buffer used for a filename string.</td>
</tr>
</tbody>
</table>
26.7.2 FTP server runtime configuration

The input buffer, the output buffer, the path buffer, the directory buffer and the filename buffer are runtime configurable.

Up to version 3.14 the compile time switches FTPS_AUTH_BUFFER_SIZE, FTPS_MAX_PATH, FTPS_MAX_PATH_DIR, FTPS_MAX_FILE_NAME and FTPS_ERR_BUFFER_SIZE were used to configure the sizes of the buffers. These compile time switches are still available to guarantee compatibility to previous versions and are used as default values for the buffer sizes in applications where the runtime configuration function IP_FTPS_ConfigBufSizes() is not called.

The compile time switches FTPS_AUTH_BUFFER_SIZE and FTPS_ERR_BUFFER_SIZE are no longer required. For further information, please refer to IP_FTPS_ConfigBufSizes on page 744.
26.7.3 FTP server system time

The FTP server requires a system time for the transmission of a complete file timestamp. FTP servers send only a piece of the timestamp of a file, either month, day and year or month, day and time. For the decision which pieces of the timestamp has to be transmitted, it compares the year of the current system time with the year which is stored in the timestamp of the file. Depending on the result of this comparison either the year or the time will be send. The following two examples show the output for both cases.

Example

1. If the value for year in the timestamp of the file is smaller then the value for year in the current system time, year will be sent:

   -rw-r--r-- 1 root 2000 Jan 1 2007 PAKET00.TXT

   In this case, the FTP client leaves this column empty or fills the missing time with 00:00. The following screenshot shows the output of the Microsoft Windows command line FTP client:

   -rw-r--r-- 1 root 9972 Jan 1 1980 PAKET00.TXT

2. If the value for year in the timestamp of the file is identical to the value for year in the current system time, the time (HH:MM) will be sent:

   -rw-r--r-- 1 root 1000 Jul 29 11:04 PAKET01.TXT

   In this case, the FTP client leaves this column empty or fills the missing year with the current year. The following screenshot shows the output of the Microsoft Windows command line FTP client:

   -rw-r--r-- 1 root 1000 Jul 29 11:04 PAKET01.TXT

In the example, the value for the current time and date is defined to 1980-01-01 00:00. Therefore, the output will be similar to example 1., since no real time clock (RTC) has been implemented. Refer to `pfGetTimeDate()` on page 742 for detailed information.
26.7.3.1 pfGetTimeDate()

Description
Returns the current system time.

Prototype

```
int (*pfGetTimeDate) ( void );
```

Return value
Current system time. If no real time clock is implemented, it should return 0x00210000 (1980-01-01 00:00)

Additional information
The format of the time is arranged as follows:
Bit 0-4: 2-second count (0-29)
Bit 5-10: Minutes (0-59)
Bit 11-15: Hours (0-23)
Bit 16-20: Day of month (1-31)
Bit 21-24: Month of year (1-12)
Bit 25-31: Number of years since 1980 (0-127)

This function pointer is used in the FTPS_APPLICATION structure. Refer to Structure FTPS_APPLICATION on page 758 for further information.

Example

```
static U32 _GetTimeDate ( void ) {
    U32 r;
    U16 Sec, Min, Hour;
    U16 Day, Month, Year;

    Sec = 0; // 0 based. Valid range: 0..59
    Min = 0; // 0 based. Valid range: 0..59
    Hour = 0; // 0 based. Valid range: 0..23
    Day = 1; // 1 based. Means that 1 is 1.
    // Valid range is 1..31 (depending on month)
    Month = 1; // 1 based. Means that January is 1. Valid range is 1..12.
    r = Sec / 2 + (Min << 5) + (Hour << 11);
    r |= (U32)(Day + (Month << 5) + (Year << 9)) << 16;
    return r;
}
```
## 26.8 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_FTPS_ConfigBufSizes()</td>
<td>Sets the buffer size used by the FTP server tasks.</td>
</tr>
<tr>
<td>IP_FTPS_CountRequiredMem()</td>
<td>Counts the memory required for one thread.</td>
</tr>
<tr>
<td>IP_FTPS_Init()</td>
<td>Initializes the application specific FTP server context.</td>
</tr>
<tr>
<td>IP_FTPS_Process()</td>
<td>Thread functionality of the FTP server.</td>
</tr>
<tr>
<td>IP_FTPS_ProcessEx()</td>
<td>Thread functionality of the FTP server.</td>
</tr>
<tr>
<td>IP_FTPS_OnConnectionLimit()</td>
<td>Sends the indication that the connection limit is reached.</td>
</tr>
<tr>
<td>IP_FTPS_SetSignOnMsg()</td>
<td>Sets the sign on message for the FTP server.</td>
</tr>
<tr>
<td>IP_FTPS_IsDataSecured()</td>
<td>Indicates if the data connection is also secured.</td>
</tr>
<tr>
<td>IP_FTPS_AllowOnlySecured()</td>
<td>Makes the server allowing only secured connections in explicit mode (FTPES).</td>
</tr>
<tr>
<td>IP_FTPS_SetImplicitMode()</td>
<td>Indicates to the server that implicit mode (FTPS) is active.</td>
</tr>
</tbody>
</table>
26.8.1  IP_FTPS_ConfigBufSizes()

Description
Sets the buffer size used by the FTP server tasks.

Prototype

void IP_FTPS_ConfigBufSizes(FTPS_BUFFER_SIZES * pBufferSizes);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBufferSizes</td>
<td>Configuration of buffer sizes.</td>
</tr>
</tbody>
</table>

For detailed information about the structure type FTPS_BUFFER_SIZES refer to Structure FTPS_BUFFER_SIZES on page 756.
26.8.2 IP_FTPS_CountRequiredMem()

Description
Counts the memory required for one thread. This can be used to determine the total re-
quired memory pool size for a configuration.

Prototype
U32 IP_FTPS_CountRequiredMem (FTPS_CONTEXT * pContext);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Context keeping track of configured settings. Can be NULL.</td>
</tr>
</tbody>
</table>

Return value
Amount of memory required for internals to handle one thread.

Additional information
In addition to the memory requirement calculated for the FTP server internals, some addi-
tional memory might be required for managing a memory pool.
26.8.3  IP_FTPS_Init()

**Description**

Initializes the application specific FTP server context. This context is specific to one connection. Has to be called if IP_FTPS_ProcessEx() is used for the task processing.

**Prototype**

```c
void IP_FTPS_Init (       FTPS_CONTEXT     *  pContext ,
const  IP_FTPS_API      *  pIP_API ,
const  IP_FS_API        *  pFS_API ,
const  FTPS_APPLICATION *  pApplication ,
const  FTPS_SYS_API     *  pSYS_API );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to the FTP server application context. This keeps track of configured settings.</td>
</tr>
<tr>
<td>pIP_API</td>
<td>Function table with API functions necessary for IP operations.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Function table with API functions for file system operations.</td>
</tr>
<tr>
<td>pApplication</td>
<td>FTP server application settings.</td>
</tr>
<tr>
<td>pSYS_API</td>
<td>Function table with API functions necessary for system operations.</td>
</tr>
</tbody>
</table>

**Additional information**

The structure type `IP_FTPS_API` contains mappings of the required socket functions to the actual IP stack. This is required because the socket functions are slightly different on different systems.

For detailed information about the used structure types, please refer to:

<table>
<thead>
<tr>
<th>Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_FTPS_API</td>
<td><em>Structure IP_FTPS_API on page 754</em></td>
</tr>
<tr>
<td>IP_FS_API</td>
<td><em>File system abstraction layer on page 1206</em></td>
</tr>
<tr>
<td>FTPS_APPLICATION</td>
<td><em>Structure FTPS_APPLICATION on page 758</em></td>
</tr>
<tr>
<td>FTPS_SYS_API</td>
<td><em>Structure FTPS_SYS_API on page 757</em></td>
</tr>
</tbody>
</table>
26.8.4 IP_FTPS_Process()

Description
Thread functionality of the FTP server. Initializes and starts the FTP server. Returns when the connection is closed or a fatal error occurs.

Prototype

```c
int IP_FTPS_Process(const IP_FTPS_API *pIP_API,
                    FTPS_SOCKET hCtrlSock,
                    const IP_FS_API *pFS_API,
                    const FTPS_APPLICATION *pApplication);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIP_API</td>
<td>Function table with API functions necessary for IP operations.</td>
</tr>
<tr>
<td>hCtrlSock</td>
<td>Handle of the control socket.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Function table with API functions for file system operations.</td>
</tr>
<tr>
<td>pApplication</td>
<td>FTP server application settings.</td>
</tr>
</tbody>
</table>

Return value

0 O.K.

Additional information

New implementations should use IP_FTPS_ConfigBufSizes(), IP_FTPS_Init() and IP_FTPS_ProcessEx() instead of IP_FTPS_Process().

The structure type IP_FTPS_API contains mappings of the required socket functions to the actual IP stack. This is required because the socket functions are slightly different on different systems.

The hCtrlSock is the socket which was created when the client has been connected to the command port (usually port 21).

For detailed information about the structure type IP_FS_API refer to File system abstraction layer on page 1206. For detailed information about the structure type FTPS_APPLICATION refer to Structure FTPS_APPLICATION on page 758.
26.8.5   IP_FTPS_ProcessEx()

Description
Thread functionality of the FTP server. Returns when the connection is closed or a fatal error occurs.

Prototype

```c
int IP_FTPS_ProcessEx(FTPS_CONTEXT * pContext,
                        FTPS_SOCKET hCtrlSock);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to the FTP server application context. This keeps track of configured settings.</td>
</tr>
<tr>
<td>hCtrlSock</td>
<td>Handle of the control socket.</td>
</tr>
</tbody>
</table>

Return value

- 0      O.K.
- ≠ 0    Error.

Additional information

The `hCtrlSock` is the socket which was created when the client has been connected to the command port (usually port 21).
### 26.8.6 IP_FTPS_OnConnectionLimit()

**Description**

Sends the indication that the connection limit is reached.

**Prototype**

```c
void IP_FTPS_OnConnectionLimit(const IP_FTPS_API * pIP_API,
                                FTPS_SOCKET hCtrlSock);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIP_API</td>
<td>Function table with API functions necessary for IP operations.</td>
</tr>
<tr>
<td>hCtrlSock</td>
<td>Handle of the control socket.</td>
</tr>
</tbody>
</table>

**Additional information**

The structure type `IP_FTPS_API` contains mappings of the required socket functions to the actual IP stack. This is required because the socket functions are slightly different on different systems.

The `hCtrlSock` is the socket which was created when the client has been connected to the command port (usually port 21).
26.8.7  IP_FTPS_SetSignOnMsg()

Description
Sets the sign on message for the FTP server.

Prototype

```c
void IP_FTPS_SetSignOnMsg(const char * sSignOnMsg);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sSignOnMsg</td>
<td>The &quot;sign on&quot; message.</td>
</tr>
</tbody>
</table>

Additional information

If not set with this function, the default sign on message from the `FTPS_SIGN_ON_MSG` define will be used.
26.8.8 IP_FTPS_IsDataSecured()

Description
Indicates if the data connection is also secured.

Prototype

```c
int IP_FTPS_IsDataSecured(const FTPS_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the FTP context.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Data connection is not secured.</td>
</tr>
<tr>
<td>1</td>
<td>Data connection is secured.</td>
</tr>
</tbody>
</table>

Additional information

If `pContext` is NULL, it is assumed that data are secured too.
26.8.9    IP_FTPS_AllowOnlySecured()

Description
Makes the server allowing only secured connections in explicit mode (FTPES). When this API is called, the command connection shall be secured. If the flag DataOnOff is set, data connection shall also be secured.

Prototype

```c
void IP_FTPS_AllowOnlySecured (FTPS_CONTEXT * pContext,
                   unsigned        DataOnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the FTP context.</td>
</tr>
<tr>
<td>DataOnOff</td>
<td>Flag to indicate if the data connection shall be also secured.</td>
</tr>
</tbody>
</table>
26.8.10  IP_FTPS_SetImplicitMode()

Description
Indicates to the server that implicit mode (FTPS) is active.

Prototype

```c
void IP_FTPS_SetImplicitMode(FTPS_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the FTP context.</td>
</tr>
</tbody>
</table>
26.9  Data structures

26.9.1  Structure IP_FTPS_API

Description
This structure contains the pointer to the socket functions which are required to use the FTP server.

Prototype

```c
typedef struct {
    int          (* pfSend )       ( const  unsigned  char *  pData ,  int  Len ,
                                            FTPS_SOCKET hSock );
    int          (* pfReceive )    (       unsigned  char *  pData ,  int  Len ,
                                            FTPS_SOCKET hSock );
    FTPS_SOCKET (* pfConnect )    ( FTPS_SOCKET hCtrlSock ,  U16 Port );
    void         (* pfDisconnect )( FTPS_SOCKET hDataSock );
    FTPS_SOCKET (* pfListen )     ( FTPS_SOCKET hCtrlSock ,  U16 *  pPort ,  U8 *  pIPAddr );
    int          (* pfAccept )     ( FTPS_SOCKET hCtrlSock ,  FTPS_SOCKET *  phDataSocket );
    int          (* pfSetSecure )  ( FTPS_SOCKET Socket ,  FTPS_SOCKET Clone );
}  IP_FTPS_API ;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfSend</td>
<td>Callback function that sends data to the client on socket level.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Callback function that receives data from the client on socket level.</td>
</tr>
<tr>
<td>pfConnect</td>
<td>Callback function that handles the connect back to a FTP client on socket level if not using passive mode.</td>
</tr>
<tr>
<td>pfDisconnect</td>
<td>Callback function that disconnects a connection to the FTP client on socket level if not using passive mode.</td>
</tr>
<tr>
<td>pfListen</td>
<td>Callback function that binds the server to a port and addr.</td>
</tr>
<tr>
<td>pfAccept</td>
<td>Callback function that accepts incoming connections.</td>
</tr>
<tr>
<td>pfSetSecure</td>
<td>Callback function that sets a FTPS_SOCKET (input command connection) as secured and eventually clone it for the output command connection. Could be NULL if TLS security is not supported.</td>
</tr>
</tbody>
</table>
26.9.2 Structure FTPS_ACCESS_CONTROL

Description
This structure contains the pointer to the access control callback functions.

Prototype

```c
typedef struct {
    int (*pfFindUser) (const char* sUser);
    int (*pfCheckPass) (int UserId, const char* sPass);
    int (*pfGetDirInfo) (int UserId, const char* sDirIn, char* sDirOut, int SizeOfDirOut);
    int (*pfGetFileInfo)(int UserId, const char* sFileIn, char* sFileOut, int SizeOfFileOut);
} FTPS_ACCESS_CONTROL;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfFindUser</td>
<td>Callback function that checks if the user is valid.</td>
</tr>
<tr>
<td>pfCheckPass</td>
<td>Callback function that checks if the password is valid.</td>
</tr>
<tr>
<td>pfGetDirInfo</td>
<td>Callback function that checks the permissions of the connected user for every directory.</td>
</tr>
<tr>
<td>pfGetFileInfo</td>
<td>Callback function that checks the permissions of the connected user for every file. May be NULL if directory permissions are sufficient for your needs.</td>
</tr>
</tbody>
</table>

Example
Refer to Access control on page 733 for an example.
26.9.3 Structure FTPS_BUFFER_SIZES

Description

This structure contains the configuration for the buffer to allocate when using IP_FTPS_ProcessEx().

Prototype

```c
typedef struct {
    U32 NumBytesInBuf;
    U32 NumBytesOutBuf;
    U32 NumBytesCwdNameBuf;
    U32 NumBytesPathNameBuf;
    U32 NumBytesDirNameBuf;
    U32 NumBytesFileNameBuf;
} IP_FTPS_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NumBytesInBuf</td>
<td>Size of Rx buffer. By default FTPS_BUFFER_SIZE.</td>
</tr>
<tr>
<td>NumBytesOutBuf</td>
<td>Size of Tx buffer. By default FTPS_BUFFER_SIZE.</td>
</tr>
<tr>
<td>NumBytesCwdNameBuf</td>
<td>Size of buffer used for the Current Working Directory. By default FTPS_MAX_PATH_DIR.</td>
</tr>
<tr>
<td>NumBytesPathNameBuf</td>
<td>Size of buffer used for paths (directory + filename). By default FTPS_MAX_PATH.</td>
</tr>
<tr>
<td>NumBytesDirNameBuf</td>
<td>Size of buffer used for dir(ectory) names (directory without filename). By default FTPS_MAX_PATH.</td>
</tr>
<tr>
<td>NumBytesFileNameBuf</td>
<td>Size of buffer used for filenames. By default FTPS_MAX_FILE_NAME.</td>
</tr>
</tbody>
</table>
26.9.4 Structure FTPS_SYS_API

Description
This structure contains the pointers to system functions which are required to use the FTP server with `IP_FTPS_Init()` and `IP_FTPS_ProcessEx()`.

Prototype

```c
typedef struct {
    void* (*pfAlloc)(U32 NumBytesReq);
    void (*pfFree)(void* p);
} IP_FTPS_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
</table>
| pfAlloc  | Callback function that allocates memory for buffers as configured using `IP_FTPS_ConfigBufSizes()`.
| pfFree   | Callback function that frees previously allocated resources.                |
26.9.5    Structure FTPS_APPLICATION

Description
Used to store application specific parameters.

Prototype

typedef struct {
    FTPS_ACCESS_CONTROL* pAccess;
    U32 (*pfGetTimeDate) (void);
} FTPS_APPLICATION;

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAccess</td>
<td>Pointer to the FTPS_ACCESS_APPLICATION structure.</td>
</tr>
<tr>
<td>pfGetTimeDate</td>
<td>Pointer to the function which returns the current system time.</td>
</tr>
</tbody>
</table>

Additional information
For additional information to structure FTPS_ACCESS_APPLICATION refer to Structure FTPS_ACCESS_CONTROL on page 755. For additional information to function pointer pfGetTimeDate() refer to FTP server system time on page 741.

Example

/* Excerpt from OS_IP_FTPServer.c */

/*********************************************************************
*       FTPS_ACCESS_CONTROL
*       Description
* User/pass data table
*
static FTPS_ACCESS_CONTROL _Access_Control = {
    _FindUser,
    _CheckPass,
    _GetDirInfo
};

*********************************************************************
*        _GetTimeDate
*/
static U32 _GetTimeDate ( void )  {
    U32 r;
    U16 Sec ,  Min ,  Hour ;
    U16 Day ,  Month ,  Year ;
    Sec   =  0 ;          // 0 based.  Valid range: 0..59
    Min   =  0 ;          // 0 based.  Valid range: 0..59
    Hour  =  0 ;          // 0 based.  Valid range: 0..23
    Day   =  1 ;          // 1 based.  Means that 1 is 1.
                           // Valid range is 1..31 (depending on month)
    Month =  1 ;          // 1 based.  Means that January is 1.  Valid range is 1..12.
    r   =  Sec /  2  +  ( Min <<  5 )  +  ( Hour  <<  11 );
    r  |=  ( U32 )( Day +  ( Month <<  5 )  +  ( Year  <<  9 ))  <<  16 ;
    return  r ;
}

*********************************************************************
*        FTPS_APPLICATION
*       Description
* Application data table, defines all application specifics
*  used by the FTP server
*/
static const FTPS_APPLICATION _Application = {
  _Access_Control,
  _GetTimeDate
};
26.10 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the FTP server presented in the tables below have been measured on a Cortex-M4 system. Details about the further configuration can be found in the sections of the specific example.

Configuration used

```
#define FTPS_BUFFER_SIZE 512
#define FTPS_MAX_PATH 128
#define FTPS_MAX_PATH_DIR 128
#define FTPS_MAX_FILE_NAME 13
```

26.10.1 ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER’s Embedded Studio V3.12 using GCC version 6.2.1 20161205 (release) [ARM/embedded-6-branch revision 243739] (arm-none-eabi) with size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP FTP server</td>
<td>approximately 7.3 kBytes</td>
</tr>
</tbody>
</table>

26.10.2 RAM usage

Using the legacy API `IP_FTPS_Process()`, almost all of the RAM used by the FTP server is taken from task stacks. For new implementations `IP_FTPS_ProcessEx()` should be used, which allocates memory using a callback, keeping the task stack requirement low.

The amount of RAM required for every child task depends on the configuration of your server. The table below shows typical RAM requirements for your task stacks.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>ParentTask</td>
<td>Listens for incoming connections.</td>
<td>approximately 500 bytes including TCP/IP task stack.</td>
</tr>
<tr>
<td>ChildTask</td>
<td>Handles a request.</td>
<td>approximately 1800 bytes for the FTP server including TCP/IP stack (excluding filesystem).</td>
</tr>
</tbody>
</table>

**Note:** The FTP server requires at least 1 child task.

The approximately RAM usage for the FTP server buffers can be calculated by adding up all buffer sizes configured using `IP_FTPS_ConfigBufSizes()`. The function `IP_FTPS_CountRequiredMem()` can be used to retrieve the required memory for the buffers for one child task for the current configuration.

The FTP server sample is designed to help you to find the correct configuration by using `IP_FTPS_CountRequiredMem()`. In addition the sample warns you about an insufficient memory configuration.
Chapter 27

FTP client (Add-on)

The embOS/IP FTP client is an optional extension to the TCP/IP stack. The FTP client can be used with embOS/IP or with a different TCP/IP stack. All functions which are required to add a FTP client to your application are described in this chapter.
27.1 embOS/IP FTP client

The embOS/IP FTP client is an optional extension which adds the client part of FTP protocol to the stack. FTP stands for File Transfer Protocol. It is the basic mechanism for moving files between machines over TCP/IP based networks such as the Internet. FTP is a client/server protocol, meaning that one machine, the client, initiates a file transfer by contacting another machine, the server and making requests.

The FTP client implements the relevant parts of the following RFCs.

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RFC 959]</td>
<td>FTP - File Transfer Protocol</td>
</tr>
</tbody>
</table>

The following table shows the contents of the embOS/IP FTP client root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the FTP client with embOS/IP.</td>
</tr>
<tr>
<td>.\Config\</td>
<td>Contains the FTP client configuration file.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the FTP client sources.</td>
</tr>
<tr>
<td>.\IP\FS\</td>
<td>Contains the sources for the file system abstraction layer and the read-only file system. Refer to File system abstraction layer on page 1206 for detailed information.</td>
</tr>
<tr>
<td>.\Windows\FTPclient\</td>
<td>Contains the source, the project files and an executable to run embOS/IP FTP client on a Microsoft Windows host.</td>
</tr>
</tbody>
</table>
27.2 Feature list

- Low memory footprint.
- Multiple connections supported.
- Independent of the file system: Any file system can be used.
- Independent of the TCP/IP stack: Any stack with sockets can be used.
- Demo application included.
- Project for executable on PC for Microsoft Visual Studio included.
27.3 Requirements

TCP/IP stack

The embOS/IP FTP client requires a TCP/IP stack. It is optimized for embOS/IP, but any RFC-compliant TCP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and an implementation which uses the socket API of embOS/IP.
27.4 FTP basics

The File Transfer Protocol (FTP) is an application layer protocol. FTP is an unusual service in that it utilizes two ports, a ‘Data‘ port and a ‘CMD’ (command) port. Traditionally these are port 21 for the command port and port 20 for the data port. FTP can be used in two modes, active and passive. Depending on the mode, the data port is not always on port 20.

When an FTP client contacts a server, a TCP connection is established between the two machines. The server does a passive open (a socket is listen) when it begins operation; thereafter clients can connect with the server via active opens. This TCP connection persists for as long as the client maintains a session with the server, (usually determined by a human user) and is used to convey commands from the client to the server, and the server replies back to the client. This connection is referred to as the FTP command connection.

The FTP commands from the client to the server consist of short sets of ASCII characters, followed by optional command parameters. For example, the FTP command to display the current working directory is `PWD` (Print Working Directory). All commands are terminated by a carriage return-linefeed sequence (CRLF) (ASCII 10,13; or Ctrl-J, Ctrl-M). The servers replies consist of a 3 digit code (in ASCII) followed by some explanatory text. Generally codes in the 200s are success and 500s are failures. See the RFC for a complete guide to reply codes. Most FTP clients support a verbose mode which will allow the user to see these codes as commands progress.

If the FTP command requires the server to move a large piece of data (like a file), a second TCP connection is required to do this. This is referred to as the FTP data connection (as opposed to the aforementioned command connection). In active mode the data connection is opened by the server back to a listening client. In passive mode the client opens also the data connection. The data connection persists only for transporting the required data. It is closed as soon as all the data has been sent.
27.4.1 Passive mode FTP for the client

In passive mode FTP the client connects from a random unprivileged port \( P \) (\( P > 1023 \)) to the FTP server’s command port, port 21. In opposite to an active mode FTP connection where the client opens a passive port for data transmission and waits for the connection from server-side, the client sends in passive mode the “PASV” command to the server and expects an answer with the information on which port the server is listening for the data connection.

After receiving this information, the client connects to the specified data port of the server from its local data port.

**Note:** In the current version of embOS/IP, the FTP client supports only passive mode FTP. Active mode FTP will be added in one of the coming versions.

27.4.2 Connection security

When a SSL stack is present (for example emSSL), the connection could be secured. To do so the value of the `Mode` parameter of the API `IP_FTPC_Connect()` could be added with `FTPC_MODE_EXPLICIT_TLS_REQUIRED` or `FTPC_MODE_IMPLICIT_TLS_REQUIRED`.

27.4.2.1 FTP implicit mode

When a server works in implicit mode, every connections are secured from the start. It uses a different port than the regular 21 (usually 990). Thus the client has to connect to the right port and upgrade the connection to a secure one.

27.4.2.2 FTP explicit mode

When a server works in explicit mode, the connection start normally as in plain mode. Then the client sends a PROT command to request an upgrade of the connection. When the connection is secured, the exchange goes on with user and password as usual.
27.4.3  Supported FTP client commands

embOS/IP FTP client supports a subset of the defined FTP commands. Refer to [RFC 959] for a complete detailed description of the FTP commands. The following FTP commands are implemented:

<table>
<thead>
<tr>
<th>FTP commands</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDUP</td>
<td>Change to parent directory</td>
</tr>
<tr>
<td>CWD</td>
<td>Change working directory</td>
</tr>
<tr>
<td>LIST</td>
<td>List directory</td>
</tr>
<tr>
<td>MKD</td>
<td>Make directory</td>
</tr>
<tr>
<td>PASS</td>
<td>Password</td>
</tr>
<tr>
<td>PWD</td>
<td>Print the current working directory</td>
</tr>
<tr>
<td>RETR</td>
<td>Retrieve</td>
</tr>
<tr>
<td>RMD</td>
<td>Remove directory</td>
</tr>
<tr>
<td>STOR</td>
<td>Store</td>
</tr>
<tr>
<td>TYPE</td>
<td>Transfer type</td>
</tr>
<tr>
<td>USER</td>
<td>User name</td>
</tr>
<tr>
<td>PROT</td>
<td>Set protection behavior.</td>
</tr>
<tr>
<td>PBSZ</td>
<td>Set protection buffer size.</td>
</tr>
</tbody>
</table>
27.5 Configuration

The embOS/IP FTP client can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

Binary switches "B"

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

Numerical values "N"

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

Alias "A"

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

Function replacements "F"

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

27.5.1 FTP client compile time configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>FTPc_WARN</td>
<td>--</td>
<td>Defines a function to output warnings. In debug configurations (DEBUG = 1) FTPc_WARN maps to IP_Warnf_Application().</td>
</tr>
<tr>
<td>F</td>
<td>FTPc_LOG</td>
<td>--</td>
<td>Defines a function to output logging messages. In debug configurations (DEBUG = 1) FTPc_LOG maps to IP_Logf_Application().</td>
</tr>
<tr>
<td>N</td>
<td>FTPC_BUFFER_SIZE</td>
<td>512</td>
<td>Defines the size of the in and the out buffer of the FTP client. This means that the client requires the defined number of bytes for each buffer. For example, FTPC_BUFFER_SIZE = 512 means 1024 bytes RAM requirement.</td>
</tr>
<tr>
<td>N</td>
<td>FTPC_CTRL_BUFFER_SIZE</td>
<td>256</td>
<td>Defines the maximum length of the buffer used for the control channel.</td>
</tr>
<tr>
<td>N</td>
<td>FTPC_SERVER_REPLY_BUFFER_SIZE</td>
<td>128</td>
<td>Defines the maximum length of the buffer used for the server reply strings. This buffer is only required and used in debug builds. In release builds the memory will not be allocated.</td>
</tr>
</tbody>
</table>
## 27.6 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_FTPC_Connect()</td>
<td>Connects to a FTP server.</td>
</tr>
<tr>
<td>IP_FTPC_Disconnect()</td>
<td>Closes an established connection to a FTP server.</td>
</tr>
<tr>
<td>IP_FTPC_ExecCmd()</td>
<td>Executes a FTP command to the FTP server.</td>
</tr>
<tr>
<td>IP_FTPC_Init()</td>
<td>Initializes the context of the FTP client.</td>
</tr>
<tr>
<td>IP_FTPC_InitEx()</td>
<td>Initializes the context of the FTP client.</td>
</tr>
</tbody>
</table>
27.6.1 IP_FTPC_Connect()

Description
Connects to a FTP server. The complete login process including the authentication is handled by this function.

Prototype

```c
int IP_FTPC_Connect (       IP_FTPC_CONTEXT * pContext,
                           const char             * sServer,
                           const char             * sUser,
                           const char             * sPass,
                           unsigned           PortCmd,
                           unsigned           Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type IP_FTPC_CONTEXT.</td>
</tr>
<tr>
<td>sServer</td>
<td>Dot-decimal IP address of a FTP server, for example “192.168.11.55”.</td>
</tr>
<tr>
<td>sUser</td>
<td>User name if required for the authentication. Can be NULL.</td>
</tr>
<tr>
<td>sPass</td>
<td>Password if required for the authentication. Can be NULL.</td>
</tr>
<tr>
<td>PortCmd</td>
<td>Port number in listening mode on the FTP server. Generally servers are using 21.</td>
</tr>
<tr>
<td>Mode</td>
<td>FTP transfer mode. Mode is a mask describing the connection mode and the security. Mask is as follow with default (0) set to FTPC_MODE_ACTIVE and FTPC_MODE_PLAIN_FTP: • FTPC_MODE_ACTIVE or FTPC_MODE_PASSIVE. • FTPC_MODE_PLAIN_FTP or FTPC_MODE_EXPLICIT_TLS_REQUIRED or FTPC_MODE_IMPLICIT_TLS_REQUIRED.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>1</td>
<td>Error. Illegal parameter (pContext = NULL).</td>
</tr>
<tr>
<td>-1</td>
<td>Error during the process of connection establishment.</td>
</tr>
</tbody>
</table>

Additional information

The function IP_FTPC_Init() must be called before a call IP_FTPC_Connect().

Note: In the current version of embOS/IP, the FTP client supports only passive mode FTP.

Example
Refer to IP_FTPC_ExecCmd on page 772 for an example application which uses IP_FTPC_Connect().
27.6.2   IP_FTPC_Disconnect()

Description
Closes an established connection to a FTP server.

Prototype

\[
\text{int IP_FTPC_Disconnect(IP_FTPC_CONTEXT \ast pContext);}\
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{pContext}</td>
<td>Pointer to a structure of type IP_FTPC_CONTEXT.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>1</td>
<td>Error. Illegal parameter (\text{pContext} = \text{NULL})</td>
</tr>
</tbody>
</table>

Example

Refer to \text{IP_FTPC_ExecCmd} on page 772 for an example application which uses \text{IP_FTPC_Disconnect}().
27.6.3  IP_FTPC_ExecCmd()

Description
Executes a FTP command to the FTP server.

Prototype

```c
int IP_FTPC_ExecCmd(       IP_FTPC_CONTEXT *  pContext,
                         unsigned           Cmd,
                         const  char             *  sPara );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type IP_FTPC_CONTEXT.</td>
</tr>
<tr>
<td>Cmd</td>
<td>The commands to perform.</td>
</tr>
<tr>
<td>sPara</td>
<td>String with the required parameters for the command. Depending on the command, this parameter can be NULL.</td>
</tr>
</tbody>
</table>

Return value

0       Success.
1       Error. Illegal parameter (pContext = NULL).
-1      Error during command execution.

Valid values for parameter Cmd

<table>
<thead>
<tr>
<th>Valid values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FTPC_CMD_CDUP</td>
<td>The command CDUP (Change to Parent Directory). sPara is NULL.</td>
</tr>
<tr>
<td>FTPC_CMD_CWD</td>
<td>The command CWD (Change Working Directory). sPara is the path to the directory that should be accessed.</td>
</tr>
<tr>
<td>FTPC_CMD_LIST</td>
<td>The command LIST (List current directory content). sPara is NULL.</td>
</tr>
<tr>
<td>FTPC_CMD_MKD</td>
<td>The command MKD (Make directory). sPara is the name of the directory that should be created.</td>
</tr>
<tr>
<td>FTPC_CMD_PASS</td>
<td>The command PASS (Set password). sPara is the password.</td>
</tr>
<tr>
<td>FTPC_CMD_PWD</td>
<td>The command PWD (Print Working Directory). sPara is NULL.</td>
</tr>
<tr>
<td>FTPC_CMD_RETR</td>
<td>The command RETR (Retrieve). sPara is the name of the file that should be received from the server. The FTP client creates a file on the used storage medium and stores the retrieved file.</td>
</tr>
<tr>
<td>FTPC_CMD_RMD</td>
<td>The command RMD (Remove directory). sPara is the name of the directory that should be removed.</td>
</tr>
<tr>
<td>FTPC_CMD_STOR</td>
<td>The command STOR (Store). sPara is the name of the file that should be stored on the server.</td>
</tr>
<tr>
<td>Valid values</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FTPC_CMD_TYPE</td>
<td>The command TYPE (Transfer type). \texttt{sPara} is the transfer type.</td>
</tr>
<tr>
<td>FTPC_CMD_USER</td>
<td>The command USER (Set username). \texttt{sPara} is the username.</td>
</tr>
<tr>
<td>FTPC_CMD_DELE</td>
<td>The command DELE (delete file). \texttt{sPara} is the name of the file to</td>
</tr>
<tr>
<td></td>
<td>delete.</td>
</tr>
<tr>
<td>FTPC_CMD_PROT</td>
<td>The command PROT (set protection behavior). \texttt{sPara} is the value to</td>
</tr>
<tr>
<td></td>
<td>set.</td>
</tr>
<tr>
<td>FTPC_CMD_PBSZ</td>
<td>The command PBSZ (set protection buffer size). \texttt{sPara} is the value</td>
</tr>
<tr>
<td></td>
<td>to set (typically 0).</td>
</tr>
</tbody>
</table>

### Additional information

\texttt{IP_FTPC_Init()} and \texttt{IP_FTPC_Connect()} have to be called before \texttt{IP_FTPC_ExecCmd()}. Refer to \texttt{IP_FTPC_Init} on page 775 for detailed information about how to initialize the FTP client and refer to \texttt{IP_FTPC_Connect} on page 770 for detailed information about how to establish a connection to a FTP server.

\texttt{IP_FTPC_ExecCmd()} sends a command to the server and handles everything what is required on FTP client side. The commands which are listed in section Supported FTP client commands on page 663, but not explained here, are normally not directly called from the user application. There is no need to call \texttt{IP_ExecCmd()} with these commands. The FTP client uses these commands internally and sends them to the server if required. For example, the call of \texttt{IP_FTPC_Connect()} sends the the commands USER, PASS and SYST to the server and process the server replies for each of the commands, an explicit call of \texttt{IP_FTPC_Exec()} with one of these commands is not required.

### Example

```c
/* Excerpt from the example application OS_IP_FTPClient.c */

/* **************************************************************************
 *       MainTask
 * Note:
 * The size of the stack of this task should be at least
 * 1200 bytes + FTPC_CTRL_BUFFER_SIZE + 2 * FTPC_BUFFER_SIZE.
 */
void MainTask(void);
void MainTask(void) {
    IP_FTPC_CONTEXT FTPConnection;
    U8 acCtrlIn[FTPC_CTRL_BUFFER_SIZE];
    U8 acDataIn[FTPC_BUFFER_SIZE];
    U8 acDataOut[FTPC_BUFFER_SIZE];
    int r;

    // Initialize the IP stack
    //
    IP_Init();
    OS_CREATETASK(&_TCB, "IP_Task", IP_Task, 150, _IPStack); // Start the IP_Task
    // Check if target is configured
    //
    while (IP_IFaceIsReady() == 0) {
        BSP_ToggleLED(1);
        OS_Delay(50);
    }
```

// FTP client task
//
while (1) {
    BSP_SetLED(0);
    // Initialize FTP client context
    memset(&FTPConnection, 0, sizeof(FTPConnection));
    // Initialize the FTP client
    IP_FTPC_Init(&FTPConnection, &IP_Api, &IP_FS_FS, acCtrlIn, sizeof(acCtrlIn),
                 acDataIn, sizeof(acDataIn), acDataOut, sizeof(acDataOut));
    // Connect to the FTP server
                        21, FTPC_MODE_PASSIVE);
    if (r == FTPC_ERROR) {
        FTPC_LOG("APP: Could not connect to FTP server.\r\n");
        goto Disconnect;
    }
    // Change from root directory into directory "Test"
    r = IP_FTPC_ExecCmd(&FTPConnection, FTPC_CMD_CWD, "/Test/" );
    if (r == FTPC_ERROR) {
        FTPC_LOG("APP: Could not change working directory.\r\n");
        goto Disconnect;
    }
    // Upload the file "Readme.txt"
    r = IP_FTPC_ExecCmd(&FTPConnection, FTPC_CMD_STOR, "Readme.txt");
    if (r == FTPC_ERROR) {
        FTPC_LOG("APP: Could not upload data file.\r\n");
        goto Disconnect;
    }
    // Change back to root directory.
    r = IP_FTPC_ExecCmd(&FTPConnection, FTPC_CMD_CDUP, NULL);
    if (r == FTPC_ERROR) {
        FTPC_LOG("APP: Change to parent directory failed.\r\n");
        goto Disconnect;
    }
    // Disconnect.
    Disconnect:
    IP_FTPC_Disconnect(&FTPConnection);
    FTPC_LOG("APP: Done.\r\n");
    BSPClrLED(0);
    OS_Delay(10000);
}
27.6.4  IP_FTPC_Init()

Description

Initializes the context of the FTP client.

Prototype

```c
int IP_FTPC_Init(
    IP_FTPC_CONTEXT * pContext,
    const IP_FTPC_API * pIP_API,
    const IP_FS_API * pFS_API,
    U8 * pCtrlBuffer,
    unsigned NumBytesCtrl,
    U8 * pDataInBuffer,
    unsigned NumBytesDataIn,
    U8 * pDataOutBuffer,
    unsigned NumBytesDataOut);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type IP_FTPC_CONTEXT.</td>
</tr>
<tr>
<td>pIP_API</td>
<td>Pointer to a structure of type IP_FTPC_API.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Pointer to the file system API.</td>
</tr>
<tr>
<td>pCtrlBuffer</td>
<td>Pointer to the buffer used for the control channel information.</td>
</tr>
<tr>
<td>NumBytesCtrl</td>
<td>Size of the control buffer in bytes.</td>
</tr>
<tr>
<td>pDataInBuffer</td>
<td>Pointer to the buffer used to receive data from the server.</td>
</tr>
<tr>
<td>NumBytesDataIn</td>
<td>Size of the receive buffer in bytes.</td>
</tr>
<tr>
<td>pDataOutBuffer</td>
<td>Pointer to the buffer used to transmit data to the server.</td>
</tr>
<tr>
<td>NumBytesDataOut</td>
<td>Size of the transmit buffer in bytes.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success.</td>
</tr>
<tr>
<td>1</td>
<td>Invalid parameters.</td>
</tr>
</tbody>
</table>

Additional information

IP_FTPC_Init() must be called before any other FTP client function will be called. For detailed information about the structure type IP_FS_API refer to File system abstraction layer on page 1206. For detailed information about the structure type IP_FTPC_API refer to Structure IP_FTPC_API on page 777.

Example

Refer to IP_FTPC_ExecCmd on page 772 for an example application which uses IP_FTPC_Init().
27.6.5  IP_FTPC_InitEx()

Description
Initializes the context of the FTP client.

Prototype

```c
int IP_FTPC_InitEx(       IP_FTPC_CONTEXT     *  pContext ,
const  IP_FTPC_API         *  pIP_API ,
const  IP_FS_API           *  pFS_API ,
U8                  *  pCtrlBuffer ,
unsigned               NumBytesCtrl ,
U8                  *  pDataInBuffer ,
unsigned               NumBytesDataIn ,
U8                  *  pDataOutBuffer ,
unsigned               NumBytesDataOut ,
const  IP_FTPC_APPLICATION *  pApplication );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type IP_FTPC_CONTEXT.</td>
</tr>
<tr>
<td>pIP_API</td>
<td>Pointer to a structure of type IP_FTPC_API.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Pointer to the file system API.</td>
</tr>
<tr>
<td>pCtrlBuffer</td>
<td>Pointer to the buffer used for the control channel information.</td>
</tr>
<tr>
<td>NumBytesCtrl</td>
<td>Size of the control buffer in bytes.</td>
</tr>
<tr>
<td>pDataInBuffer</td>
<td>Pointer to the buffer used to receive data from the server.</td>
</tr>
<tr>
<td>NumBytesDataIn</td>
<td>Size of the receive buffer in bytes.</td>
</tr>
<tr>
<td>pDataOutBuffer</td>
<td>Pointer to the buffer used to transmit data to the server.</td>
</tr>
<tr>
<td>NumBytesDataOut</td>
<td>Size of the transmit buffer in bytes.</td>
</tr>
<tr>
<td>pApplication</td>
<td>Pointer to a structure of type IP_FTPC_APPLICATION.</td>
</tr>
</tbody>
</table>

Return value

0      Success.
1      Invalid parameters.
27.7 Data structures

27.7.1 Structure IP_FTPC_API

Description
This structure contains the pointer to the socket functions which are required to use the FTP client.

Prototype

```c
typedef struct {
    FTPC_SOCKET (*pfConnect) (const char * SrvAddr, unsigned SrvPort);
    void          (*pfDisconnect)  (FTPC_SOCKET Socket);
    int           (*pfSend)        (const char * pData, int Len, FTPC_SOCKET Socket);
    int           (*pfReceive)     (char * pData, int Len, FTPC_SOCKET Socket);
    int           (*pfSetSecure)   (FTPC_SOCKET Socket, FTPC_SOCKET Clone);
} IP_FTPC_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfConnect</td>
<td>Callback function that handles the connect to a FTP server on socket level.</td>
</tr>
<tr>
<td>pfDisconnect</td>
<td>Callback function that disconnects a connection to the FTP server on socket level.</td>
</tr>
<tr>
<td>pfSend</td>
<td>Callback function that sends data to the FTP server on socket level.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Callback function that receives data from the FTP server on socket level.</td>
</tr>
<tr>
<td>pfSetSecure</td>
<td>Callback function to configure the socket as secured and eventually clone it (<code>Clone</code> might be NULL). This is used when secured connections with SSL are supported. Set this pointer to NULL if no security is present.</td>
</tr>
</tbody>
</table>
27.7.2 Structure IP_FTPC_APPLICATION

Description
This structure contains a callback that will be called for every received lines when getting a reply from the server.

Prototype

```c
typedef struct {
    void (*pfReply)(IP_FTPC_CONTEXT* pContext,
                    unsigned        Cmd,
                    const char*     sResponse,
                    unsigned        ResponseLength,
                    unsigned        IsLineComplete);
} IP_FTPC_APPLICATION;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfReply</td>
<td>Callback.</td>
</tr>
<tr>
<td>pfReply\pContext</td>
<td>Pointer on the FTP client context.</td>
</tr>
<tr>
<td>pfReply\Cmd</td>
<td>Command id.</td>
</tr>
<tr>
<td>pfReply\sResponse</td>
<td>Server reply.</td>
</tr>
<tr>
<td>pfReply\sResponseLength</td>
<td>Server reply length.</td>
</tr>
<tr>
<td>pfReply\IsLineComplete</td>
<td>Last line indication.</td>
</tr>
</tbody>
</table>
27.8 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the FTP client presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

Configuration used

```c
#define FTPC_BUFFER_SIZE 512
#define FTPC_CTRL_BUFFER_SIZE 256
#define FTPC_SERVER_REPLY_BUFFER_SIZE 128  // Only required in debug builds
                                              // with enabled logging.
```

27.8.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP FTP client</td>
<td>approximately 2.0 kBytes</td>
</tr>
</tbody>
</table>

27.8.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP FTP client</td>
<td>approximately 1.7 kBytes</td>
</tr>
</tbody>
</table>

27.8.3 RAM usage

Almost all of the RAM used by the web server is taken from task stacks. The amount of RAM required for every child task depends on the configuration of your client. The table below shows typical RAM requirements for your task stacks.

<table>
<thead>
<tr>
<th>Build</th>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Release</td>
<td>A task used for the FTP client without debugging features and disabled debug outputs.</td>
<td>approximately 500 bytes</td>
</tr>
</tbody>
</table>

The approximately task stack size required for the FTP client can be calculated as follows:

\[
\text{TaskStackSize} = 2 \times \text{FTPC_BUFFER_SIZE} + \text{FTPC_CTRL_BUFFER_SIZE}
\]

<table>
<thead>
<tr>
<th>Build</th>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug</td>
<td>A task used for the FTP client with debugging features and enabled debug outputs.</td>
<td>approximately 500 bytes</td>
</tr>
</tbody>
</table>

The approximately task stack size required for the FTP client can be calculated as follows:

\[
\text{TaskStackSize} = 2 \times \text{FTPC_BUFFER_SIZE} + \text{FTPC_CTRL_BUFFER_SIZE} + \text{FTPC_SERVER_REPLY_BUFFER_SIZE}
\]
Chapter 28

TFTP client/server

The TFTP (Trivial File Transfer Protocol) is an extension to the TCP/IP stack. All functions which are required to add a TFTP client or a TFPT server to your application are described in this chapter.
28.1 embOS/IP TFTP

The embOS/IP TFTP is an extension which adds the TFTP protocol to the stack. TFTP stands for Trivial File Transfer Protocol. It is the basic mechanism for moving files via UDP between machines over IP based networks. TFTP is a client/server protocol, meaning that one machine, the client, initiates a file transfer by contacting another machine, the server and making requests. The server must be operating before the client initiates his requests.

The TFTP server implements the relevant parts of the following RFCs.

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>
28.2 Feature list

- Low memory footprint.
- Independent of the file system: Any file system can be used.
- Independent of the TCP/IP stack: Any stack with sockets can be used.
- Demo application included.
28.3  TFTP basics

The Trivial File Transfer Protocol (TFTP) is an application layer protocol.

When a TFTP client contacts a server, a UDP command is sent to the server's port. The traditional port is 69. The command sent is either a read or a write request. The client will send data always to the server's port whereas the server will respond with data to the port on that the client is sending.

The TFTP requests are sent in a RFC conform format.
28.4 Using the TFTP samples

Ready to use examples for embOS/IP are supplied. The sample applications are configured to work with each other but can be used with any TFTP client/server with minimal modification. The example applications require a file system to make data files available. Refer to File system abstraction layer on page 868 for detailed information.

28.4.1 Running the TFTP server example on target hardware

The embOS/IP TFTP sample applications should always be the first step to check the proper function of the TFTP client/server with your target hardware.

Add all source files located in the following directories (and their subdirectories) to your project and update the include path:

- Application
- Config
- Inc
- IP
- IP\IP_FS\[NameOfUsedFileSystem]

It is recommended that you keep the provided folder structure.

The sample applications can be used on the most targets without the need for changing any of the configuration flags.
### 28.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_TFTP_InitContext()</td>
<td>Initializes the context for storing connection parameters of a TFTP client/server.</td>
</tr>
<tr>
<td>IP_TFTP_RecvFile()</td>
<td>Requests a file from a TFTP server.</td>
</tr>
<tr>
<td>IP_TFTP_SendFile()</td>
<td>Sends a data file to a TFTP server.</td>
</tr>
<tr>
<td>IP_TFTP_ServerTask()</td>
<td>TFTP server task that can be be started in a separate task.</td>
</tr>
</tbody>
</table>
28.5.1 IP_TFTP_InitContext()

Description
Initializes the context for storing connection parameters of a TFTP client/server.

Prototype

```c
int IP_TFTP_InitContext(       TFTP_CONTEXT * pContext,
                               unsigned IFace,
                               const IP_FS_API * pFS_API,
                               char * pBuffer,
                               int BufferSize,
                               U16 ServerPort);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type TFTP_CONTEXT.</td>
</tr>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pFS_API</td>
<td>Pointer to the used file system API.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to buffer for storing transfer data. Needs to be big enough to hold</td>
</tr>
<tr>
<td></td>
<td>the biggest TFTP message (512 bytes payload + 4 bytes TFTP header).</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of buffer assigned with pBuffer.</td>
</tr>
<tr>
<td>ServerPort</td>
<td>Port of the server. Can be 0 if the structure is used to connect as a client</td>
</tr>
<tr>
<td></td>
<td>or if the default TFTP port (69) should be used.</td>
</tr>
</tbody>
</table>

Return value

- 0    Success.
- < 0  Error, typically buffer too small or no buffer set.

Additional information

A static structure of TFTP_CONTEXT needs to be supplied by the application to provide space to store connection parameters.
28.5.2 IP_TFTP_RecvFile()

Description
Requests a file from a TFTP server.

Prototype

```c
int IP_TFTP_RecvFile(TFTP_CONTEXT * pContext,
unsigned IFace,
U32 IPAddr,
U16 Port,
const char * sFileName,
int Mode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type TFTP_CONTEXT.</td>
</tr>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>IPAddr</td>
<td>IP addresse of TFTP server.</td>
</tr>
<tr>
<td>Port</td>
<td>Port of TFTP server listening.</td>
</tr>
<tr>
<td>sFileName</td>
<td>Name of the file to retrieve from server.</td>
</tr>
<tr>
<td>Mode</td>
<td>TFTP_MODE_OCTET.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>≥ 0</td>
<td>O.K.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error</td>
</tr>
</tbody>
</table>

Additional information

A static structure of TFTP_CONTEXT needs to initialized with IP_TFTP_InitContext() before using it with this function.
### 28.5.3 IP_TFTP_SendFile()

**Description**
Sends a data file to a TFTP server.

**Prototype**
```c
int IP_TFTP_SendFile(       TFTP_CONTEXT *  pContext ,
unsigned        IFace ,
U32            IPAddr ,
U16            Port ,
const  char          *  sFileName ,
int             Mode );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a structure of type TFTP_CONTEXT.</td>
</tr>
<tr>
<td>IFace</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>IPAddr</td>
<td>IP address of TFTP server.</td>
</tr>
<tr>
<td>Port</td>
<td>Port of TFTP server listening.</td>
</tr>
<tr>
<td>sFileName</td>
<td>Name of file to send to server.</td>
</tr>
<tr>
<td>Mode</td>
<td>TFTP_MODE_OCTET.</td>
</tr>
</tbody>
</table>

**Return value**

- ≥ 0  O.K.
- < 0  Error.

**Additional information**

A static structure of TFTP_CONTEXT needs to be initialized with IP_TFTP_InitContext() before using it with this function.
28.5.4   IP_TFTP_ServerTask()

Description
TFTP server task that can be be started in a separate task.

Prototype

```c
void IP_TFTP_ServerTask(void * pPara);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPara</td>
<td>Casted pointer to a structure of type TFTP_CONTEXT.</td>
</tr>
</tbody>
</table>

Additional information

A static structure of TFTP_CONTEXT needs to initialized with IP_TFTP_InitContext() before using it with this function. The task does never return.
28.6 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the TFTP client/server presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

28.6.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP TFTP client</td>
<td>approximately 1.2 kBytes</td>
</tr>
<tr>
<td>embOS/IP TFTP server</td>
<td>approximately 1.2 kBytes</td>
</tr>
</tbody>
</table>

28.6.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP TFTP client</td>
<td>approximately 1.2 kBytes</td>
</tr>
<tr>
<td>embOS/IP TFTP server</td>
<td>approximately 1.2 kBytes</td>
</tr>
</tbody>
</table>

28.6.3 RAM usage

Each connection requires approximately 550 bytes of RAM that split into space for the required transfer buffer (app. 516 bytes) and the space for TFTP_CONTEXT.
Chapter 29

PPP / PPPoE (Add-on)

The embOS/IP implementation of the Point to Point Protocol (PPP) is an optional extension to embOS/IP. It can be used to establish a PPP connection over Ethernet (PPPoE) or using modem to connect via telephone carrier. All functions that are required to add PPP/PPPoE to your application are described in this chapter.
29.1 embOS/IP PPP/PPPoE

The embOS/IP PPP implementation is an optional extension which can be seamlessly integrated into your TCP/IP application. It combines a maximum of performance with a small memory footprint. The PPP implementation allows an embedded system to connect via Point to Point Protocol to a network.

The PPP module implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RFC 1334]</td>
<td>PPP Authentication Protocols</td>
</tr>
<tr>
<td>[RFC 1661]</td>
<td>The Point-to-Point Protocol (PPP)</td>
</tr>
<tr>
<td>[RFC 2516]</td>
<td>A Method for Transmitting PPP Over Ethernet (PPPoE)</td>
</tr>
</tbody>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the PPP implementation with embOS/IP.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the PPP sources, IP_PPP.c, IP_PPP_CP.c, IP_PPP_IPCP.c, IP_PPP_LCP.c, IP_PPP_Line.c, IP_PPP_PAP.c and IP_PPP_PoE.c. Additionally to the main source code files of the PPP add-on an example implementation for the connection of a modem via USART (IP_Modem_USART.c) is supplied.</td>
</tr>
</tbody>
</table>
29.2 Feature list

- Low memory footprint.
- Support PAP authentication protocol
- Support for PPP over Ethernet.
29.3 Requirements

TCP/IP stack

The embOS/IP PPP implementation requires the embOS/IP TCP/IP stack. Your modem has to be able to be configured to respond in the format:

"<CR><LF><Response>"
29.4 PPP backgrounds

The Point to Point Protocol is a link layer protocol for establishing a direct connection between two network nodes.

Using PPP, an embOS/IP application can establish a PPP connection to a PPP server. The handshaking mechanism includes normally an authentication process. The current version of embOS/IP supports the following authentication schemes:

- **PAP** - Password Authentication Protocol
## 29.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PPPoE functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_PPPOE_AddInterface()</td>
<td>Adds a PPPoE interface.</td>
</tr>
<tr>
<td>IP_PPPOE_ConfigRetries()</td>
<td>Configures the number of times to resend a lost message before breaking the connection.</td>
</tr>
<tr>
<td>IP_PPPOE_Reset()</td>
<td>Resets a PPPoE session.</td>
</tr>
<tr>
<td>IP_PPPOE_SetAuthInfo()</td>
<td>Sets the authentication information for the PPPoE connection.</td>
</tr>
<tr>
<td>IP_PPPOE_SetUserCallback()</td>
<td>Sets a callback function to inform the user about a status change.</td>
</tr>
<tr>
<td><strong>PPP functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_PPP_AddInterface()</td>
<td>Adds a PPP driver.</td>
</tr>
<tr>
<td>IP_PPP_OnRx()</td>
<td>Receives one or more characters from the hardware.</td>
</tr>
<tr>
<td>IP_PPP_OnRxChar()</td>
<td>Receives a character from the hardware (typ.</td>
</tr>
<tr>
<td>IP_PPP_OnTxChar()</td>
<td>Sends a character via PPP.</td>
</tr>
<tr>
<td>IP_PPP_SetUserCallback()</td>
<td>Sets a callback function to inform the user about a status change.</td>
</tr>
<tr>
<td><strong>Modem functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_MODEM_Connect()</td>
<td>Initializes a PPP connect on a modem using the passed AT command.</td>
</tr>
<tr>
<td>IP_MODEM_Disconnect()</td>
<td>Disconnects the connection established with a modem on a specific interface.</td>
</tr>
<tr>
<td>IP_MODEM_GetResponse()</td>
<td>Retrieves a pointer to the responses received since the last sent AT command.</td>
</tr>
<tr>
<td>IP_MODEM_SendString()</td>
<td>Sends an AT command to the modem without waiting for an answer.</td>
</tr>
<tr>
<td>IP_MODEM_SendStringEx()</td>
<td>Sends an AT command to the modem and waits for the expected response with a timeout or checks for responses received in multiple parts.</td>
</tr>
<tr>
<td>IP_MODEM_SetAuthInfo()</td>
<td>Sets authentication information if needed for the connection to establish.</td>
</tr>
<tr>
<td>IP_MODEM_SetConnectTimeout()</td>
<td>Sets the connect timeout to wait for a requested connection with IP_MODEM_Connect() to be established.</td>
</tr>
<tr>
<td>IP_MODEM_SetInitCallback()</td>
<td>Sets a callback that is used to initialize the modem before actually starting the connection attempt.</td>
</tr>
<tr>
<td>IP_MODEM_SetInitString()</td>
<td>Sets an initialization string that is sent to the modem before actually starting the connection attempt.</td>
</tr>
<tr>
<td>IP_MODEM_SetSwitchToCmdDelay()</td>
<td>Sets the delay that is applied before and after the “++ATH” command that is used to switch back the modem from data to command mode.</td>
</tr>
</tbody>
</table>
29.6 PPPoE functions
29.6.1  IP_PPPOE_AddInterface()

Description
Adds a PPPoE interface.

Prototype

```c
int IP_PPPOE_AddInterface(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

≥ 0  Index of the new interface.
29.6.2 IP_PPPOE_ConfigRetries()

Description
Configures the number of times to resend a lost message before breaking the connection.

Prototype

```c
void IP_PPPOE_ConfigRetries(unsigned IFaceId,
                          U32 NumTries,
                          U32 Timeout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>NumTries</td>
<td>Number of times the stack will resend the message.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout in ms before a resend is triggered.</td>
</tr>
</tbody>
</table>
29.6.3 IP_PPPOE_Reset()

Description
Resets a PPPoE session. The PPPoE layer is closed by sending a PADT if connected. Also resets the PPP connection state, but does not send any more PPP packets.

Prototype

```c
void IP_PPPOE_Reset(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
29.6.4 IP_PPPOE_SetAuthInfo()

Description
Sets the authentication information for the PPPoE connection.

Prototype

```c
void IP_PPPOE_SetAuthInfo( unsigned IFaceId,
                           const char * sUser,
                           const char * sPass );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>sUser</td>
<td>PPPoE user name.</td>
</tr>
<tr>
<td>sPass</td>
<td>PPPoE user password.</td>
</tr>
</tbody>
</table>
29.6.5 IP_PPPOE_SetUserCallback()

Description
Sets a callback function to inform the user about a status change.

Prototype

```c
void IP_PPPOE_SetUserCallback(U32 IFaceId,
                              IP_PPPOE_INFORM_USER_FUNC * pfInformUser);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pfInformUser</td>
<td>Pointer to a user function of type IP_PPPOE_INFORM_USER_FUNC. which is called when a status change occurs.</td>
</tr>
</tbody>
</table>

Additional information

Callback function will only be added if IP_PPPOE_AddInterface() has been called before. IP_PPPOE_INFORM_USER_FUNC is defined as follows:

```c
typdef void (IP_PPPOE_INFORM_USER_FUNC)(U32 IFaceId, U32 Status);
```
29.7 PPP functions
29.7.1  IP_PPP_AddInterface()

Description

Adds a PPP driver.

Prototype

```c
int IP_PPP_AddInterface (const IP_PPP_LINE_DRIVER * pLineDriver, int ModemIndex);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pLineDriver</td>
<td>Pointer to a structure IP_PPP_LINE_DRIVER.</td>
</tr>
<tr>
<td>ModemIndex</td>
<td>Modem index; Fixed to 0.</td>
</tr>
</tbody>
</table>

Return value

≥ 0  Index of the interface.
29.7.2 IP_PPP_OnRx()

Description
Receives one or more characters from the hardware. Uses IP_PPP_OnRxChar() to receive the characters one by one.

Prototype

```c
void IP_PPP_OnRx ( IP_PPP_CONTEXT * pContext ,
                   U8 * pData ,
                   int NumBytes );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to a Structure IP_PPP_CONTEXT.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to a buffer which is storing the received data.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes to receive.</td>
</tr>
</tbody>
</table>
29.7.3   IP_PPP_OnRxChar()

Description
Receives a character from the hardware (typ. modem). Checks if the received character is an escape character, removes the escape character if required and stores the character into packet buffer. When a complete packet is received, it is given to the stack.

Prototype

```c
void IP_PPP_OnRxChar ( IP_PPP_CONTEXT * pContext,
                       U8               Data );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pContext</code></td>
<td>Pointer to a structure IP_PPP_CONTEXT.</td>
</tr>
<tr>
<td><code>Data</code></td>
<td>1 received character.</td>
</tr>
</tbody>
</table>
29.7.4 IP_PPP_OnTxChar()

Description
Sends a character via PPP. The function checks if the character needs an escape character for the HDLC framing and sends the escape character if required.

Prototype

```c
int IP_PPP_OnTxChar(unsigned Unit);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unit</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

0   More data has been sent. Keep Tx interrupt enabled.
1   No more data to send. Disable Tx interrupt if necessary.
29.7.5  IP_PPP_SetUserCallback()

Description
Sets a callback function to inform the user about a status change.

Prototype

```c
void  IP_PPP_SetUserCallback ( U32                       IFaceId ,
                              IP_PPP_INFORM_USER_FUNC * pfInformUser );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pfInformUser</td>
<td>Pointer to a user function of type IP_PPP_INFORM_USER_FUNC which is called when a status change occurs.</td>
</tr>
</tbody>
</table>

Additional information

Callback function will only be added if IP_PPP_AddInterface() has been called before.

**IP_PPP_INFORM_USER_FUNC is defined as follows:**

```c
typedef void (IP_PPP_INFORM_USER_FUNC)(U32 IFaceId, U32 Status);
```
29.8 Modem functions
29.8.1 IP_MODEM_Connect()

Description

Initializes a PPP connect on a modem using the passed AT command.

Prototype

```c
int IP_MODEM_Connect(const char * sATCommand);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sATCommand</td>
<td>AT command string to dial up a connection. Must not use &lt;CR&gt; at the end of the dial string. Typically this is the command “ATD” followed by a dial number.</td>
</tr>
</tbody>
</table>

Return value

= 0  Connected
≠ 0  Error

Example

```c
IP_MODEM_Connect("ATD*99***1#");
```
29.8.2 IP_MODEM_Disconnect()

Description
Disconnects the connection established with a modem on a specific interface.

Prototype

```c
void IP_MODEM_Disconnect(unsigned IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Example

```c
IP_MODEM_Disconnect(0);
```
29.8.3   IP_MODEM_GetResponse()

Description
Retrieves a pointer to the responses received since the last sent AT command. It is able to copy the response into a provided buffer if necessary.

Prototype

```c
char  * IP_MODEM_GetResponse ( unsigned    IFaceId ,
char      *  pBuffer ,
unsigned    NumBytes ,
unsigned  *  pNumBytesInBuffer );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to the buffer where the response shall be copied to. May be NULL.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Size of the buffer pointed to by pBuffer.</td>
</tr>
<tr>
<td>pNumBytesInBuffer</td>
<td>Number of bytes in receive buffer. May be NULL.</td>
</tr>
</tbody>
</table>

Return value

= NULL  No response in buffer. The last response might have already been cleared to receive the response for the next command.
≠ NULL   Pointer to buffer that holds the last response received. Beginning <CR><LF> is skipped.

Example

```c
U8  aBuffer[256];
unsigned  NumBytesReceived;
IP_MODEM_SendString(0, "AT");
IP_MODEM_GetResponse(0, &aBuffer[0], sizeof(aBuffer), &NumBytesReceived);
```
29.8.4  IP_MODEM_SendString()

Description
Sends an AT command to the modem without waiting for an answer.

Prototype

```c
void  IP_MODEM_SendString (       unsigned    IFaceId ,
                                 const    char      *  sCmd );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>sCmd</td>
<td>AT command to be sent.</td>
</tr>
</tbody>
</table>

Additional information

This routine is meant for sending simple AT commands to the modem that do not need to be checked for their response.

It is not designed to be used with IP_MODEM_GetResponse(). If you intend to process the modem response please use IP_MODEM_SendStringEx() instead.
29.8.5  IP_MODEM_SendStringEx()

Description
Sends an AT command to the modem and waits for the expected response with a timeout or checks for responses received in multiple parts.

Prototype

```c
int IP_MODEM_SendStringEx(unsigned IFaceId, const char * sCmd, const char * sResponse, unsigned Timeout, unsigned RecvBufOffs);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>sCmd</td>
<td>AT command to be sent. May be NULL.</td>
</tr>
<tr>
<td>sResponse</td>
<td>Expected response without &lt;CR&gt;&lt;LF&gt; in front. May be NULL.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout to wait for any response in ms.</td>
</tr>
<tr>
<td>RecvBufOffs</td>
<td>Can be used to check for a response that is sent in multiple parts.</td>
</tr>
</tbody>
</table>

Return value

0  OK, correct response received.
1  Timeout.
2  Wrong response received.

Additional information

Sending a new command with IP_MODEM_SendString() clears the buffer of previous received responses.

RecvBufOffs can be used to check for responses that are sent by the modem in multiple responses. If not passed '0' the receive buffer will not be cleared to not clear out already received following responses from the previously sent command. RecvBufOffs id the offset in bytes from the beginning of the first received response. Being able to receive responses that are sent in multiple parts is necessary as some command may be responded with a confirm for the command sent itself and respond with a second message after an undefined time.

Example sending a command and checking for its response with a timeout

```c
IP_MODEM_SendStringEx(0, "AT", "OK", 100, 0);
```

Example for checking the SIM status of a GSM modem

```c
int r;
// Check if the modem is waiting for a SIM PIN to be entered
r = IP_MODEM_SendStringEx(0, "AT+CPIN\r", "+CPIN: SIM PIN", 1000, 0);
if (r == 0) {
    // The modem is waiting for the PIN to be entered
    IP_MODEM_SendString(0, "AT^SSET=1\r"); // Enable "^SSIM READY" response once
    // the SIM data has been read
```

© 2010-2019 SEGGER Microcontroller GmbH
IP_OS_Delay(100);
//
// Enter SIM PIN. The OK response will arrive quickly. The modem then
// reads data from the SIM.
//
IP_MODEM_SendStringEx(0, "AT+CPIN="1234"\r", "OK", 15000, 0);
//
// After receiving the "OK" response for the command the modem will need an
// undefined time to read data from the SIM. The modem sends the response
// "^SSIM READY" once it has finished. We will receive the response at an
// 6 byte offset (OK<CR><LF><CR><LF>^SSIM READY).
//
IP_MODEM_SendStringEx(0, NULL, "^SSIM READY", 15000, 6);
}
else {
//
// The modem does not seem to wait for a PIN, check if the modem
// reports "READY". This means no PIN is set for the SIM card. In this case
// the modem responds with "+CPIN: READY" that will be located at offset 0
// in the receive buffer.
//
if (IP_MEMCMP(IP_MODEM_GetResponse(0, NULL, 0, NULL), "+CPIN: READY", 12) != 0) {
    IP_Panic("Unrecognized response from modem.");
}
}
29.8.6  IP_MODEM_SetAuthInfo()

Description
Sets authentication information if needed for the connection to establish.

Prototype

```c
void IP_MODEM_SetAuthInfo(       unsigned    IFaceId,
                                const  char      *  sUser,
                                const  char      *  sPass );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>sUser</td>
<td>String containing the user name to be used.</td>
</tr>
<tr>
<td>sPass</td>
<td>String containing the password to be used.</td>
</tr>
</tbody>
</table>

Additional information
Setting a user name and a password is only necessary when required by your ISP.

Example

```c
IP_MODEM_SetAuthInfo(0, "User", "Pass");
```
29.8.7  IP_MODEM_SetConnectTimeout()

Description
Sets the connect timeout to wait for a requested connection with IP_MODEM_Connect() to be established.

Prototype

```
void IP_MODEM_SetConnectTimeout(unsigned IFaceId, unsigned ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>ms</td>
<td>Timeout in ms. Default 15s.</td>
</tr>
</tbody>
</table>

Example

```
IP_MODEM_SetConnectTimeout(0, 30000);
```
29.8.8   IP_MODEM_SetInitCallback()

Description
Sets a callback that is used to initialize the modem before actually starting the connection attempt. The callback is called from IP_MODEM_Connect().

Prototype

void  IP_MODEM_SetInitCallback ( void  (* pfInit)());

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfInit</td>
<td>Void callback routine for initialization of the modem before connecting.</td>
</tr>
</tbody>
</table>

Example

```c
static void _InitModem ( void )
{
    IP_MODEM_SendString ( 0 ,  "AT" );
}

IP_MODEM_SetInitCallback ( _InitModem );
IP_MODEM_Connect ( "ATD*99***1#" );
```
29.8.9  IP_MODEM_SetInitString()

Description
Sets an initialization string that is sent to the modem before actually starting the connection attempt. In case IP_MODEM_SetInitCallback() is used the init string is not sent.

Prototype

```c
void  IP_MODEM_SetInitString ( const  char  *  sInit );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sInit</td>
<td>Command to be sent to the modem before connecting.</td>
</tr>
</tbody>
</table>

Example

```c
IP_MODEM_SetInitString("ATE0V1");
IP_MODEM_Connect("ATD*99***1#");
```
29.8.10 IP_MODEM_SetSwitchToCmdDelay()

Description
Sets the delay that is applied before and after the “+++ATH” command that is used to
switch back the modem from data to command mode.

Prototype

void IP_MODEM_SetSwitchToCmdDelay(unsigned IFaceId,
                                  unsigned ms);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>ms</td>
<td>Timeout in ms between sending “+++” and “ATH”.</td>
</tr>
</tbody>
</table>

Additional information
Sending “+++ATH” to switch back to command mode and then hanging up the connection
is fine to be sent in one message. For some modem this does not apply. They need some
time to switch back to command mode before accepting “ATH” for hanging up.
# 29.9 Data structures

<table>
<thead>
<tr>
<th>Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PPP_CONTEXT</td>
<td>Structure which stores the information about the PPP connection.</td>
</tr>
<tr>
<td>RESEND_INFO</td>
<td>A structure which stores the resend condition for different stages of the PPP connection.</td>
</tr>
<tr>
<td>IP_PPP_LINE_DRIVER</td>
<td>Structure with pointers to application related functions.</td>
</tr>
</tbody>
</table>
29.9.1 Structure IP_PPP_CONTEXT

Description

A structure which stores the information about the PPP connection.

Prototype

```c
typedef struct IP_PPP_CONTEXT {
    PPP_SEND_FUNC * pfSend;
    PPP_TERM_FUNC * pfTerm;
    PPP_INFORM_USER_FUNC * pfInformUser;
    void * pSendContext;
    int NumBytesPrepend;
    U8 IFaceId;
    struct {
        U32 NumTries;
        I32 Timeout;
    } Config;
    struct {
        U8 Id;
        U8 aOptCnt[MAX_OPT];
        PPP_LCP_STATE AState;
        PPP_LCP_STATE PState;
        RESEND_INFO Resend;
        U16 MRU;
        U32 ACCM;
        U32 OptMask;
    } LCP;
    struct {
        U8 Id;
        U8 aOptCnt[MAX_OPT];
        PPP_CCP_STATE AState;
        PPP_CCP_STATE PState;
        RESEND_INFO Resend;
        U32 OptMask;
    } CCP;
    struct {
        U8 Id;
        U8 aOptCnt[MAX_OPT];
        PPP_IPCP_STATE AState;
        PPP_IPCP_STATE PState;
        RESEND_INFO Resend;
        IP_ADDR IpAddr;
        IP_ADDR aDNSServer[IP_MAX_DNS_SERVERS];
        U32 OptMask;
    } IPCP;
    struct {
        U8 UserLen;
        U8 abUser[64];
        U8 PassLen;
        U8 abPass[64];
        U16 Prot;
        U32 Data;
        PPP_AUTH_STATE State;
        RESEND_INFO Resend;
        U32 OptMask;
    } Auth;
    IP_PPP_LINE_DRIVER * pLineDriver;
} IP_PPP_CONTEXT;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
### 29.9.2 Structure RESEND_INFO

**Description**
A structure which stores the resend condition for different stages of the PPP connection.

**Prototype**

```c
typedef struct {
    IP_PACKET * pPacket;
    I32 Timeout;
    I32 InitialTimeout;
    U32 RemTries;
    #if IP_DEBUG
    const char * sPacketName;
    #endif
} RESEND_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPacket</td>
<td>Pointer to an IP_PACKET structure.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout in ms before a resend is triggered.</td>
</tr>
<tr>
<td>InitialTimeout</td>
<td>Initial timeout in ms before a resend is triggered. Saved to be able to reset Timeout to it's original state.</td>
</tr>
<tr>
<td>RemTries</td>
<td>Counter for the remaining number of retries.</td>
</tr>
<tr>
<td>sPacketName</td>
<td>(Only with IP_DEBUG ≥ 1.) Custom name assigned to the packet.</td>
</tr>
</tbody>
</table>
29.9.3 Structure IP_PPP_LINE_DRIVER

Description
Structure with pointers to application related functions.

Prototype

```
typedef struct {
    void (*pfInit) (struct IP_PPP_CONTEXT * pPPPContext);
    void (*pfSend) (U8 Data);
    void (*pfSendNext) (U8 Data);
    void (*pfTerminate) (U8 IFaceId);
    void (*pfOnPacketCompletion) (void);
} IP_PPP_LINE_DRIVER;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfInit</td>
<td>Pointer to a function which initializes the PPP connection.</td>
</tr>
<tr>
<td>pfSend</td>
<td>Pointer to a function which sends the first byte.</td>
</tr>
<tr>
<td>pfSendNext</td>
<td>Pointer to a function which sends the next byte. Typically called from an interrupt that confirms that the last byte has been sent.</td>
</tr>
<tr>
<td>pfTerminate</td>
<td>Pointer to a function which terminates the connection.</td>
</tr>
<tr>
<td>pfOnPacketCompletion</td>
<td>Optional. Called when packet is complete. Normally used for packet oriented PPP interfaces GPRS or USB modems.</td>
</tr>
</tbody>
</table>
29.10  PPPoE resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the PPP/PPPoE modules presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

The resource usage of a typical PPPoE scenario with 1 WAN interface has been measured.

29.10.1  ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>-ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP PPP used for PPPoE</td>
<td>approximately 7.0 kBytes</td>
</tr>
</tbody>
</table>

29.10.2  ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP PPP used for PPPoE</td>
<td>approximately 6.5 kBytes</td>
</tr>
</tbody>

Chapter 30

NetBIOS (Add-on)

The embOS/IP implementation of the Network Basic Input/Output System Protocol (NetBIOS) is an optional extension to embOS/IP. It can be used to resolve NetBIOS names in a local area network. All functions that are required to add NetBIOS to your application are described in this chapter.
30.1 embOS/IP NetBIOS

The embOS/IP NetBIOS implementation is an optional extension which can be seamlessly integrated into your application. It combines a maximum of performance with a small memory footprint. The NetBIOS implementation allows an embedded system to resolve NetBIOS names in the local area network.

The NetBIOS module implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RFC 1001]</td>
<td>NetBIOS Concepts and methods</td>
</tr>
<tr>
<td>[RFC 1002]</td>
<td>NetBIOS Detailed Specifications</td>
</tr>
</tbody>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the NetBIOS implementation with embOS/IP.</td>
</tr>
<tr>
<td>.\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the NetBIOS sources IP_Netbios.c.</td>
</tr>
</tbody>
</table>
30.2 Feature list

- Low memory footprint.
- Seamless integration with the embOS/IP stack.
- Client based NetBIOS name resolution.
30.3 Requirements

TCP/IP stack
The embOS/IP NetBIOS implementation requires the embOS/IP TCP/IP stack.
30.4 NetBIOS backgrounds

The Network Basic Input/Output System protocol is an API on top of the TCP/IP protocol, it provides a way of communication between separate computers within a local area network via the session layer.

Using NetBIOS, an embOS/IP application can resolve a NetBIOS name to an IP address in the local area network.
## 30.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetBIOS</td>
<td></td>
</tr>
<tr>
<td>IP_NETBIOS_Init()</td>
<td>Initializes the NetBIOS Name Service client.</td>
</tr>
<tr>
<td>IP_NETBIOS_Start()</td>
<td>Starts the NetBIOS client Creates an UDP socket to receive NetBIOS Name Service requests.</td>
</tr>
<tr>
<td>IP_NETBIOS_Stop()</td>
<td>Stops the NetBIOS client Closes the UDP socket.</td>
</tr>
</tbody>
</table>
30.5.1  IP_NETBIOS_Init()

Description
Initializes the NetBIOS Name Service client.

Prototype

```c
int IP_NETBIOS_Init(       U32               IFaceId,
                           const  IP_NETBIOS_NAME *  paHostnames,
                           U16               LPort);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>paHostnames</td>
<td>Pointer to an array of Structure IP_NETBIOS_NAME. Expects last index to be filled with zero.</td>
</tr>
<tr>
<td>LPort</td>
<td>Local port used for listening. Typically 137. If parameter LPort is 0, 137 will be used.</td>
</tr>
</tbody>
</table>

Return value

- `< 0`  Error, invalid NetBIOS name.
- `> 0`  Ok, Number of valid NetBIOS names assigned to the target.
30.5.2  IP_NETBIOS_Start()

Description
Starts the NetBIOS client Creates an UDP socket to receive NetBIOS Name Service requests.

Prototype

\[
\text{int IP\_NETBIOS\_Start(U32 IFaceId);}
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

Return value

\[
\begin{align*}
= 0 & \quad \text{Error, could not create an UDP socket.} \\
> 0 & \quad \text{OK, number of the socket which is used for the NetBIOS Name Service.}
\end{align*}
\]
30.5.3  IP_NETBIOS_Stop()

Description
Stops the NetBIOS client Closes the UDP socket.

Prototype

```c
void IP_NETBIOS_Stop(U32 IFaceId);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>
30.5.4 Structure IP_NETBIOS_NAME

Description
A structure which stores the information about the NetBIOS name.

Prototype

```c
typedef struct IP_NETBIOS_NAME {
    char * sName;
    U8 NumBytes;
} IP_NETBIOS_NAME;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sName</td>
<td>Pointer to a string which stores the NetBIOS name.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of the NetBIOS name without termination.</td>
</tr>
</tbody>
</table>
30.6 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the NetBIOS module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

30.6.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NetBIOS module</td>
<td>approximately 0.8 kBytes</td>
</tr>
</tbody>
</table>

30.6.2 ROM usage on a Cortex-M3 system

The following resource usage has been measured on a Cortex-M3 system using IAR Embedded Workbench V6.30.6, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NetBIOS module</td>
<td>approximately 0.7 kBytes</td>
</tr>
</tbody>
</table>

30.6.3 RAM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NetBIOS module</td>
<td>approximately 26 bytes</td>
</tr>
</tbody>
</table>
Chapter 31

SNTP client (Add-on)

The embOS/IP implementation of the Simple Network Time Protocol (SNTP) client is an optional extension to embOS/IP. It can be used to request a timestamp with the current time from a NTP server. All functions that are required to add SNTP client functionality to your application are described in this chapter.
31.1 embOS/IP SNTP client

The embOS/IP SNTP client implementation is an optional extension which can be seamlessly integrated into your application. It combines a maximum of performance with a small memory footprint. The SNTP client implementation allows an embedded system to use real timestamps from a remote NTP server without using a RTC or to initialize a RTC. The SNTP protocol is based on SNTP v4.

The SNTP client module implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP SNTP client root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\IP\</td>
<td>Contains the SNTPc sources IP_SNTPC.c.</td>
</tr>
</tbody>
</table>
31.2 Feature list

- Low memory footprint.
- Seamless integration with the embOS/IP stack.
- Time synchronization with a remote NTP server.
31.3 Requirements

TCP/IP stack

The embOS/IP SNTPc implementation requires the embOS/IP TCP/IP stack.
31.4 SNTP backgrounds

The SNTP protocol is an API on top of the TCP/IP protocol, it provides a way of synchronizing the target time with a local or remote NTP server over the network.

Using SNTP, an embOS/IP application can synchronize its time with a NTP server either in the local network or in a remote network to use a timestamp with the current date and time or to initialize its own RTC with a good start value.

31.4.1 The NTP timestamp

The NTP timestamp used is represented by a 64-bit value consisting of two 32-bit fields. The first 32-bit field contains the complete seconds passed since January 1st 1900. The second 32-bit field contains fractions of a second in 2^32 picoseconds.

More information about the NTP timestamp can be found in RFC 1305.
31.4.2 The epoch problem (year 2036 problem)

The NTP timestamp reserves only 32-bit for full seconds passed which equals a little bit more than 136 years. As the NTP time is based on January 1st 1900 this means that the timestamp will overlap back to 0 some time in 2036. A timestamp older than a reference timestamp can be interpreted as valid time as well as long as it does not count up to the reference timestamp.

Based on this solution there are several possible ways of extending this period even more:

- The simplest solution to extend the timestamp to be used for around 136 years is for the target to remember the date it was built or has its firmware changed and can then use this timestamp as reference extending the NTP timestamp for further 136 years.
- Storing the current year in non volatile memory using it as reference in which epoch the target runs.
- Using other sources as reference for the epoch such as timestamps from other sources.
### 31.5 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SNTP client</td>
<td></td>
</tr>
<tr>
<td><code>IP_SNTPC_ConfigTimeout()</code></td>
<td>Configures the maximum time to wait for a response from a NTP server.</td>
</tr>
<tr>
<td><code>IP_SNTPC_GetTimeStampFromServer()</code></td>
<td>Requests the actual time from a NTP server.</td>
</tr>
</tbody>
</table>
31.5.1   IP_SNTPC_ConfigTimeout()

Description
Configures the maximum time to wait for a response from a NTP server

Prototype

```c
void IP_SNTPC_ConfigTimeout(unsigned ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms</td>
<td>Timeout in ms.</td>
</tr>
</tbody>
</table>
31.5.2 IP_SNTPC_GetTimeStampFromServer()

**Description**

Requests the actual time from a NTP server. Server is passed via punctual IP address or DNS name.

**Prototype**

```c
int IP_SNTPC_GetTimeStampFromServer(unsigned IFaceId,
                                    const char * sServer,
                                    IP_NTP_TIMESTAMP * pTimestamp);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>sServer</td>
<td>String containing either dotted decimal IP address (129.250.35.251) or DNS name (us.pool.ntp.org) of NTP server.</td>
</tr>
<tr>
<td>pTimestamp</td>
<td>Pointer where to store the received timestamp.</td>
</tr>
</tbody>
</table>

**Return value**

- $= 0$  IP_SNTPC_STATE_NO_ANSWER, Request sent but no answer from server received within timeout.
- $= 1$  IP_SNTPC_STATE_UPDATED, Timestamp updated from server response.
- $= 2$  IP_SNTPC_STATE_KOD, Server sent Kiss-Of-Death and wants us to use another server.
- $< 0$ Other, Error
31.5.3 Structure IP_NTP_TIMESTAMP

Description
A structure which stores the timestamp from a NTP request.

Prototype

```c
typedef struct IP_NTP_TIMESTAMP {
    U32 Seconds;
    U32 Fractions;
} IP_NTP_TIMESTAMP;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>Seconds passed since start of epoch, typically January 1st 1900.</td>
</tr>
<tr>
<td>Fractions</td>
<td>Fractions of a second in 232 picoseconds.</td>
</tr>
</tbody>
</table>
31.6 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the SNTP module presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

31.6.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP SNTP client</td>

Chapter 32

PTP Ordinary Clock (Add-on)

The embOS/IP implementation of the Precision Time Protocol (PTP) is an optional extension to embOS/IP. It can be used to synchronize an embedded system with a master clock in its local network. All functions that are required to add PTP functionality to your application are described in this chapter.
### 32.1 embOS/IP PTP

The embOS/IP PTP implementation is an optional extension which can be seamlessly integrated into your application. It combines a maximum of performance with a small memory footprint. This implementation covers PTP version 2 for ordinary slave-only clocks with the Delay/Response mechanism. Only one interface is supported at a time as multi-interface implementation would require master support.

The PTPv2 protocol allows an embedded system to have a precise synchronization with a master clock present in its local network. This master clock sends periodically timing related messages. The PTP protocol defines also “Management” messages in order to modify the parameters of the systems present in the network.

Some hardwares support PTP and allow to reach a precision in the order of microsecond or bellow. To reach this high precision, the driver should be updated to support PTP. This is done by adding a PTP specific driver. When there is no hardware support or no driver support, a full-software solution is used with less precision.

The PTP module implements the mandatory parts of the following IEEE Standard.

<table>
<thead>
<tr>
<th>IEEE-Std</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\IP\</td>
<td>Contains the PTP Ordinary Clock add-on IP_PT-P_OC.c. If available and purchased, a driver for hardware timestamps for a specific network interface IP_DRIVER_NAME_PTP.c might be included as well.</td>
</tr>
</tbody>
</table>
32.2 Feature list

- Low memory footprint.
- Seamless integration with the embOS/IP stack.
- Time synchronization with a remote PTP master clock.
- Support of Management messages to allow system configuration.
32.3 Requirements

TCP/IP stack

The embOS/IP PTP implementation requires the embOS/IP TCP/IP stack. Although it is working with a complete software solution, a hardware supporting PTP and an associated driver is needed to reach a higher precision.
32.4 PTP background

The PTP protocol is an API on top of the UDP/IP protocol or plain Ethernet. It provides a way of synchronizing the target with a master clock over the local network.

PTP messages are sent using multicast messages:
- Over UDP IPv4: multicast IP address is 224.0.1.129.
- Over Ethernet: multicast MAC address is 01:1B:19:00:00:00.
- Over UDP IPv6: multicast IP address is FF0X::181 (In this implementation X is set to 2 which corresponds to link-local multicast).

In case more than one master clock is present in the local network, a decision needs to be done which clock is the best master clock. This decision is done by comparing the parameters periodically sent by every master clock. The best master clock is then used as the reference called the GrandMaster clock.

Parameters that define a clock (like priority, description, ...) can be obtained (and for some parameters modified) using "Management" messages. See the IEEE1588-2008 specification for more details.

Using PTP, an embOS/IP system can synchronize its time with a PTP master clock in its local network by obtaining the transmission/reception timestamp of a series of messages between the master and the slave. With these timestamps, the slave is able to compute the time offset and the propagation time between both clocks.

This series of messages for the Delay/Response mechanism occurs periodically in order to correct the deviation of the slave time with respect to the master.
At $t_1$ the master clock sends a Sync message. It either contains $t_1$ or it is followed by a Follow-Up with $t_1$ value.

The slave stores at which time $t_2$ it receives the Sync message.

The slave sends a $\text{Delay}_\text{Req}$ and stores at which time $t_3$ the message is sent.

The master sends to the slave in a $\text{Delay}_\text{Resp}$ at which time $t_4$ it has received the $\text{Delay}_\text{Req}$.

At the end, the slave has $t_1$, $t_2$, $t_3$ and $t_4$ and can compute the time offset.

Note that this implementation is not compatible with PTP version 1. Peer-to-peer synchronization mechanism is also not supported. And as previously stated this implementation is for slave-only ordinary clocks. Similarly the specification defines optional features that are currently not supported.

### 32.4.1 Time representation

The PTP timestamp is represented by a structure of two 32-bit fields. The first 32-bit field contains the complete seconds passed since the EPOCH. The other 32-bit field contains the sub-second part of the time passed since the EPOCH expressed in nanoseconds.

The EPOCH of a PTP system could be any reference used by the grandmaster clock of the network, but generally GPS TAI is used as reference with an EPOCH set to January the
1st 1970. The Temps Atomique International (TAI), the international atomic time is currently ahead of UTC by 37 seconds and always ahead of GPS by 19 seconds.

A nice live view of different time representations live can be found at the following location: http://leapsecond.com/java/gpsclock.htm

32.4.2 Hardware support

The embOS/IP PTP add-on is able to work without the support of hardware. In this case is uses a global IP callback that retrieves the time in microseconds. A default callback is provided that uses the internal milliseconds time. It is possible to provide a more precise function with IP_SetMicrosecondsCallback().

If the hardware supports PTP, a PTP driver can be added during the configuration with IP_NI_AddPTPDriver(). Hardware based timestamps are of course more precise than any software timestamp.

The structure IP_PACKET (accessible using the zero-copy interface) contains the timestamp of arrival in seconds and nanoseconds for received packets (or time in microseconds when PTP is not available in the driver).
32.5 PTP configuration

The embOS/IP PTP ordinary clock can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

32.5.1 Configuration macro types

The following types of configuration macros exist:

Binary switches "B"

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

Numerical values "N"

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

Alias "A"

A macro which operates like a simple text substitute. An example would be the define U8, which the preprocessor would replace with unsigned char.

Function replacements "F"

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

32.5.2 Configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>IP_SUPPORT_PTP</td>
<td>0</td>
<td>Activates the support of PTP in the stack, in the driver and in the PTP module itself.</td>
</tr>
</tbody>
</table>
## 32.6 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PTP functionality</strong></td>
<td></td>
</tr>
<tr>
<td><code>IP_PTP_GetTime()</code></td>
<td>Retrieves the current PTP time based on the HW (driver) or based on OS Time.</td>
</tr>
<tr>
<td><code>IP_PTP_OC_Start()</code></td>
<td>Initializes and starts the PTP synchronization process.</td>
</tr>
<tr>
<td><code>IP_PTP_OC_Halt()</code></td>
<td>Stops the PTP messages processing.</td>
</tr>
<tr>
<td><strong>Optional PTP driver support</strong></td>
<td></td>
</tr>
<tr>
<td><code>IP_NI_AddPTPDriver()</code></td>
<td>Adds a PTP driver for HW timestamp support.</td>
</tr>
<tr>
<td><strong>Optional configuration</strong></td>
<td></td>
</tr>
<tr>
<td><code>IP_PTP_OC_SetProductDescription()</code></td>
<td>Configures the product description of the ordinary clock.</td>
</tr>
<tr>
<td><code>IP_PTP_OC_SetUserDescription()</code></td>
<td>Configures the user description of the ordinary clock.</td>
</tr>
<tr>
<td><code>IP_PTP_OC_SetRevision()</code></td>
<td>Configures the revision of the ordinary clock.</td>
</tr>
</tbody>
</table>
32.6.1 IP_PTP_GetTime()

Description
Retrieves the current PTP time based on the HW (driver) or based on OS Time.

Prototype

```c
int IP_PTP_GetTime(IP_PTP_TIMESTAMP * pPTPTimestamp);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPTPTimestamp</td>
<td>Pointer to a IP_PTP_TIMESTAMP structure (seconds and nanoseconds).</td>
</tr>
</tbody>
</table>

Return value

- = 0 Time is synchronized and based on HW time from driver.
- = 1 Time is synchronized and based on OS time (no driver support).
- = 2 PTP module not in slave state. No indication on the validity of the given time.
- < 0 Error.
32.6.2  IP_PTP_OC_Start()

**Description**
Initializes and starts the PTP synchronization process. Opens PTP specific UDP ports.

**Prototype**

```c
int IP_PTP_OC_Start(unsigned IFaceId);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
</tbody>
</table>

**Return value**

- = 0      OK.
- < 0      Unable to start.

**Additional information**

PTP uses the MAC address in order to define the clock identity. It is mandatory to call this API after having set the MAC address (i.e. after a call to `IP_SetHWAddr()` or `IP_SetHWAddrEx()`).

PTP ordinary clock supports only one active interface.
32.6.3  IP_PTP_OC_Halt()

Description
Stops the PTP messages processing. Closes the UDP ports.

Prototype

```
int IP_PTP_OC_Halt (void);
```

Return value

- \( = 0 \)  OK.
- \( < 0 \)  Error.
32.6.4  IP_NI_AddPTPDriver()

**Description**

Adds a PTP driver for HW timestamp support.

**Prototype**

```c
int IP_NI_AddPTPDriver(       unsigned            IFaceId ,
                           const  IP_HW_PTP_DRIVER *  pPTPDriver ,
                           U32                CoreClock );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index.</td>
</tr>
<tr>
<td>pPTPDriver</td>
<td>PTP driver to add.</td>
</tr>
<tr>
<td>CoreClock</td>
<td>CPU clock [Hz] of the system. Can not be 0.</td>
</tr>
</tbody>
</table>

**Return value**

- -1  Error, not supported
- 0   OK
- 1   Error, called after driver initialization has been completed.
32.6.5 IP_PTP_OC_SetProductDescription()

Description
Configures the product description of the ordinary clock.

Prototype

```
void IP_PTP_OC_SetProductDescription(char * pDesc);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDesc</td>
<td>NULL terminated string containing the description.</td>
</tr>
</tbody>
</table>

Additional information

Product description contains 3 items separated by a semi-colon:

```
<Manufacturer_name>;<model_number>;<instance_identifier>
```

The maximum length is 64.
May be left undefined.
32.6.6  IP_PTP_OC_SetUserDescription()

Description
Configures the user description of the ordinary clock.

Prototype

```c
void IP_PTP_OC_SetUserDescription(char * pDesc);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDesc</td>
<td>NULL terminated string containing the description.</td>
</tr>
</tbody>
</table>

Additional information

User description contains 2 items separated by a semi-colon:

`<Name_of_the_device>;<Physical_location_of_the_device>`

The maximum length is 128.

The `<Name_of_the_device>` field represents a user-defined name for the define (e.g. Sensor1). The `<Physical_location_of_the_device>` field is a user-defined location (e.g. Rack-2 Shelf-3). One or both of the field could be left unset. For example, valid definitions are: "Sensor1;Rack-2 Shelf-3", "Sensor1" or ";Rack-2 Shelf-3".

May be left undefined.
32.6.7  IP_PTP_OC_SetRevision()

Description
Configures the revision of the ordinary clock.

Prototype

```c
void IP_PTP_OC_SetRevision(char * pDesc);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDesc</td>
<td>NULL terminated string containing the description.</td>
</tr>
</tbody>
</table>

Additional information
Revision contains 3 items separated by a semi-colon: <HW>;<FW>;<SW>
They correspond to the revision indications of the 3 items. One or more item could be left empty, for example: HW;;SW.
The maximum length is 32.
May be left undefined.
32.6.8  Structure IP_PTP_TIMESTAMP

**Description**

A structure which stores the PTP timestamp. This is the time passed since the EPOCH of the system.

**Prototype**

```c
typedef struct IP_PTP_TIMESTAMP {
    U32 Seconds;
    U32 Nanoseconds;
} IP_PTP_TIMESTAMP;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seconds</td>
<td>Seconds passed since start of epoch of the network, typically since January 1st 1970 for GPS.</td>
</tr>
<tr>
<td>Nanoseconds</td>
<td>The sub-second part of the time passed since the EPOCH expressed in nanoseconds.</td>
</tr>
</tbody>
</table>
32.7 Resource usage
The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the PTP client presented in the tables below have been measured on a Cortex-M4 system with the default configuration.

32.7.1 ROM usage on a Cortex-M4 system
The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

Chapter 33

NTP client (Add-on)

The embOS/IP implementation of the Network Time Protocol (NTP) client is an optional extension to embOS/IP. It can be used to get current time from NTP servers. All functions that are required to add NTP client functionality to your application are described in this chapter.
33.1 embOS/IP NTP client

The embOS/IP NTP client implementation is an optional extension which can be seamlessly integrated into your application. The NTP client implementation allows an embedded system to use real timestamps from a remote NTP server without using a Real Time Clock (RTC). The NTP protocol is based on NTP v4.

The NTP client module implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP NTP client root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\IP\</td>
<td>Contains the NTP client sources IP_NTP_CLIENT.c.</td>
</tr>
</tbody>
</table>
33.2 Feature list

- Low memory footprint.
- Seamless integration with the embOS/IP stack.
- Time synchronization with remote NTP servers.
33.3 Requirements

TCP/IP stack

The embOS/IP NTP client implementation requires the embOS/IP TCP/IP stack. In order to use a server pool, a DNS environment needs to be present and configured.
33.4 NTP backgrounds

The NTP protocol is a service on top of the UDP/IP protocol, it provides a way of synchronizing the target time with a local or remote NTP server over the network.

Using NTP, an embOS/IP application can synchronize its time with a NTP server either in the local network or in a remote network to use a timestamp with the current date and time or to initialize its own RTC with a good start value.

33.4.1 The NTP timestamp

The NTP timestamp used is represented by a 64-bit value consisting of two 32-bit fields. The first 32-bit field contains the complete seconds passed since January 1st 1900. The second 32-bit field contains fractions of a second in 2^32 picoseconds.

Instead of using this structure, a unsigned 64 bits variable (U64) bit could be used with seconds in the upper 32 bits part and fraction in the lower 32 bits part.

More information about the NTP timestamp can be found in RFC 5905.

Note

In order to work, the embOS/IP NTP client add-on requires timestamp in IP packets. The switch IP_SUPPORT_PACKET_TIMESTAMP shall be set to 1.
33.4.2 The epoch problem (year 2036 problem)

The NTP timestamp reserves only 32-bit for full seconds passed which equals a little bit more than 136 years. As the NTP time is based on January 1st 1900 this means that the timestamp will overlap back to 0 some time in 2036. A timestamp older than a reference timestamp can be interpreted as valid time as well as long as it does not count up to the reference timestamp.

Based on this the offset to the OS clock is initialized at January 2017.

33.4.3 Algorithm and memory

Although the time conversion is quite simple, the NTP algorithm requires many computation and memory usage. From a measurement on a server, some parameters are computed (like delay, dispersion,...) and for every monitored server the last height of these parameters should be kept to enter the mitigation algorithm which will choose the best clocks to use for the time correction.

The full RFC implementation cost many RAM and computation power. In order to mitigate this issue on embedded targets, embOS/IP NTP client add-on proposes along with the full RFC implementation, a simpler (not RFC compliant) but less demanding implementation, activated through a compilation switch.

Another bias to the standard is that the NTP module will always be a client only. It always indicates itself as not synchronized to the other clocks in the network, so it won’t be used as a reference.

33.4.4 NTP server pool

To synchronize its time, the embOS/IP NTP client uses server clocks. There are three sources to populate its list of server clocks that work simultaneously:

- User defined clock through the APIs IP_NTP_CLIENT_AddServerClock() and IP_NTP_CLIENT_AddServerClockIPv6().
- Local clocks which broadcast periodically their time on UDP port 123 will also be used.
- Usage of server pool.

A server pool is a network name (i.e. “0.pool.ntp.org”). When a DNS request is sent for its address, the DNS reply provides in general four IP addresses of four different clocks.

In order to use this pool mechanism request, a DNS server should be present in the network and its address known by embOS/IP either by configuration or given by the DHCP server for example.

33.4.5 Time function

The embOS/IP NTP client add-on uses an IP callback to retrieve the current time in microseconds. By default a function is provided which uses IP_OS_GetTime32() in milliseconds. It is possible to provide a clock with a better precision using IP_SetMicrosecondsCallback(). For example when using embOS:

```c
IP_SetMicrosecondsCallback(OS_GetTime_us64);
```
33.5 NTP client configuration

The embOS/IP NTP client can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

33.5.1 Configuration macro types

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

33.5.2 Configuration switches

</tr>
<tr>
<td>IP_NTP_GetTimestamp()</td>
<td>Returns the current NTP time in timestamp format.</td>
</tr>
<tr>
<td>IP_NTP_GetTime()</td>
<td>Returns the current NTP time in NTP U64 format.</td>
</tr>
</tbody>
</table>
33.6.1 IP_NTP_CLIENT_Start()

Description
Starts the NTP processing and open the corresponding UDP ports.

Prototype

```c
int IP_NTP_CLIENT_Start(void);
```

Return value

- 0  Success.
- < 0  Error.

Additional information

In order for NTP to work, it is needed to call first `IP_NTP_CLIENT_Start()` and then call periodically `IP_NTP_CLIENT_Run()`.

Example

Example of a code that starts the embOS/IP NTP client, runs it and gets every 5s the current time:

```c
Time = IP_OS_GetTime32() + 5000;
//
// Start the NTP client.
//
IP_NTP_CLIENT_Start();
//
for (;;) {
    //
    // Run the NTP state machine.
    //
    IP_NTP_CLIENT_Run();
    //
    // Every 5s, print the current time.
    //
    if (IP_IsExpired(Time) != 0) {
        //
        // Next expiry in 5s.
        //
        Time += 5000;
        //
        // Get the NTP time.
        //
        NTPTime = IP_NTP_GetTime(&Status);
        //
        // Pretty print of the current time.
        //
        _PrintNTPTime(NTPTime, Status);
    }
    //
    // Give some time to other lower priority tasks to run.
    //
    OS_Delay(10);
}
### 33.6.2 IP_NTP_CLIENT_Halt()

**Description**

Stops the NTP message processing and closes the corresponding UDP ports.

**Prototype**

```c
int IP_NTP_CLIENT_Halt(unsigned ClearUserDefined);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ClearUserDefined</td>
<td>Flag to clear or keep user defined clocks.</td>
</tr>
</tbody>
</table>

**Return value**

- `= 0` Success.
- `< 0` Error.

**Additional information**

Halt doesn’t reset the time offset thus a call to `IP_NTP_GetTime()` or `IP_NTP_GetTime-stamp()` is still possible.
33.6.3  IP_NTP_CLIENT_Run()

Description
NTP management function to be called periodically.

Prototype

```c
int IP_NTP_CLIENT_Run(void);
```

Return value

= 0  Success.
< 0  NTP is not initialized (no call to start).

See `IP_NTP_CLIENT_Start` on page 881 for an example.
33.6.4 IP_NTP_CLIENT_AddServerPool()

Description
Adds a server pool where to look for clocks.

Prototype

```c
int IP_NTP_CLIENT_AddServerPool(unsigned IFaceId,
                                const char * sPool);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index on which the pool could be reached.</td>
</tr>
<tr>
<td>sPool</td>
<td>Null terminated string with the pool address.</td>
</tr>
</tbody>
</table>

Return value

- `= 0` The pool was added.
- `< 0` The pool was not added (list is full)

Additional information

It is possible to add NTP_MAX_POOL pool.

The string gives the address of the pool, for example “0.pool.ntp.org”.

In order to resolve the pool and get servers addresses, a DNS request is sent. It is needed to have a DNS server in the network to use this feature.

Example

```c
IP_NTP_CLIENT_Start();
//
// Configure maximum 4 pools.
//
IP_NTP_CLIENT_AddServerPool(_IFaceId, "0.pool.ntp.org");
IP_NTP_CLIENT_AddServerPool(_IFaceId, "1.pool.ntp.org");
IP_NTP_CLIENT_AddServerPool(_IFaceId, "2.pool.ntp.org");
IP_NTP_CLIENT_AddServerPool(_IFaceId, "3.pool.ntp.org");
```
33.6.5  IP_NTP_CLIENT_FavorLocalClock()

Description
Sets the flag to favor clock found on local network and user defined clocks.

Prototype

```c
void  IP_NTP_CLIENT_FavorLocalClock(unsigned  OnOff);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OnOff</td>
<td>Flag to set.</td>
</tr>
</tbody>
</table>

Additional information

Clock on local network should broadcast regularly their time to be identified.

When the full RFC is used, this has only an impact on the survivors list. A local clock would be anyway discarded if it doesn’t pass the clock filter algorithm.
33.6.6  IP_NTP_CLIENT_AddServerClock()

Description
Adds a user defined clock by its IPv4 IP address.

Prototype

`void IP_NTP_CLIENT_AddServerClock(unsigned IFaceId, U32 IPAddr);`

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index on which the clock is reachable.</td>
</tr>
<tr>
<td>IPAddr</td>
<td>IP address in host byte order.</td>
</tr>
</tbody>
</table>

Example

```c
// Configure a local clock.
//
IP_NTP_CLIENT_AddServerClock(_IFaceId, IP_BYTES2ADDR(192, 168, 5, 10));
```
33.6.7 IP_NTP_CLIENT_AddServerClockIPv6()

Description
Adds a user defined clock by its IPv6 IP address.

Prototype

```c
void IP_NTP_CLIENT_AddServerClockIPv6(unsigned IFaceId,
U8 * pIPAddr);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFaceId</td>
<td>Zero-based interface index on which the clock is reachable.</td>
</tr>
<tr>
<td>pIPAddr</td>
<td>Pointer on the 16 bytes of the IPv6 address.</td>
</tr>
</tbody>
</table>

Notes

To use this function, the IPv6 add-on should be present and activated (`IP_SUPPORT_IPV6` is 1).
### 33.6.8 IP_NTP_GetTimestamp()

**Description**

Returns the current NTP time in timestamp format.

**Prototype**

```c
int IP_NTP_GetTimestamp (IP_NTP_TIMESTAMP * pTimestamp);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pTimestamp</td>
<td>Pointer on the structure filled with the current time.</td>
</tr>
</tbody>
</table>

**Return value**

-1  
NTP is not started.

1  
NTP is started but not synced to a master clock.

0  
NTP is started and synced.

Refer to *Structure IP_NTP_TIMESTAMP* on page 852 in SNTP chapter.
33.6.9  IP_NTP_GetTime()

Description
Returns the current NTP time in NTP U64 format.

Prototype

U64 IP_NTP_GetTime(int * pStatus);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pStatus</td>
<td>Variable giving indication on the time validity (could be NULL).&lt;br&gt;• -1: NTP is not started.&lt;br&gt;• 1: NTP is started but not synced to a master clock.&lt;br&gt;• 0: NTP is started and synced.</td>
</tr>
</tbody>
</table>

Return value
Current time in NTP 64 bits format.

Additional information
The current time in NTP 64 bits format contains the seconds in the higher 32 bits and the fraction part in the lower 32 bits.
33.7 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the NTP client presented in the tables below have been measured on a Cortex-M4 system with the default configuration.

33.7.1 Full RFC configuration

The switch NTP_USE_SIMPLER_VERSION is set to 0.

33.7.1.1 ROM usage on a Cortex-M4 system full RFC

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NTP client with IPv6</td>
<td>approximately 4.8 kBytes</td>
</tr>
<tr>
<td>embOS/IP NTP client without IPv6</td>
<td>approximately 4.5 kBytes</td>
</tr>
</tbody>
</table>

33.7.1.2 RAM usage full RFC

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NTP client with IPv6</td>
<td>approximately 3.4 kBytes</td>
</tr>
<tr>
<td>embOS/IP NTP client without IPv6</td>
<td>approximately 3.2 kBytes</td>
</tr>
</tbody>
</table>

33.7.2 Simpler configuration

The switch NTP_USE_SIMPLER_VERSION is set to 1 (default).

33.7.2.1 ROM usage on a Cortex-M4 system simpler version

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NTP client with IPv6</td>
<td>approximately 3.4 kBytes</td>
</tr>
<tr>
<td>embOS/IP NTP client without IPv6</td>
<td>approximately 3.1 kBytes</td>
</tr>
</tbody>
</table>

33.7.2.2 RAM usage simpler version

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP NTP client with IPv6</td>
<td>approximately 0.8 kBytes</td>
</tr>
<tr>
<td>embOS/IP NTP client without IPv6</td>
<td>approximately 0.6 kBytes</td>
</tr>
</tbody>
</table>
Chapter 34

SNMP agent (Add-on)

The embOS/IP Simple Network Management Protocol (SNMP) agent is an optional extension to embOS/IP. The SNMP agent can be used with embOS/IP or with a different UDP/IP stack. All functions that are required to add an SNMP agent to your application are described in this chapter.

Although SNMP can grow very complex very fast, the embOS/IP SNMP agent aims to be easily usable for anyone, even if you do not have too much in depth knowledge about SNMP at all. Therefore the API is kept to a minimum while still providing everything necessary for a full SNMP agent implementation.
34.1 embOS/IP SNMP agent

The embOS/IP SNMP agent is an optional extension which adds SNMP agent functionality to the stack. It combines a maximum of performance with a small memory footprint. The SNMP agent allows an embedded system to handle SNMP requests from an SNMP manager and sending TRAP and INFORM messages to managers. It comes with all features typically required by embedded systems: Maximum flexibility, easily portable and low RAM usage. RAM usage has been kept to a minimum by smart buffer handling.

The SNMP agent implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP SNMP agent root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>..\Application\</td>
<td>Contains the example application to run the SNMP agent with embOS/IP.</td>
</tr>
<tr>
<td>..\Config\</td>
<td>Contains the SNMP agent configuration file. Refer to SNMP agent configuration on page 911 for detailed information.</td>
</tr>
<tr>
<td>..\Inc\</td>
<td>Contains the required include files.</td>
</tr>
<tr>
<td>..\IP\</td>
<td>Contains the SNMP agent sources and header files, IP_SSNMP_AGENT*.</td>
</tr>
<tr>
<td>..\Windows\IP\SNMP_Agent\</td>
<td>Contains the source, the project files and an executable to run the embOS/IP SNMP agent on a Microsoft Windows host. Refer to Using the SNMP agent samples on page 904 for detailed information.</td>
</tr>
</tbody>
</table>
34.2 Feature list

- Low memory footprint.
- Only few SNMP knowledge required.
- Easy MIB tree setup.
- Supports SNMPv1 and SNMPv2c.
- Supports SNMPv1 & SNMPv2 TRAP messages.
- Supports SNMPv2 INFORM messages.
- MIB-II support (System and Interfaces branch) for embOS/IP out of the box.
- Easy to use API for all typical SNMP types (Unsigned32, Counter32, ...).
- Independent of the TCP/IP stack: any stack with sockets can be used.
- Can even be used without sockets e.g. with zero-copy API.
- Demo with custom sample MIB with sockets or zero-copy API included.
- Project for executable on PC for Microsoft Visual Studio included.
34.3 SNMP agent requirements

TCP/IP stack
The embOS/IP SNMP agent requires an UDP/IP stack. It is optimized for embOS/IP, but any RFC-compliant UDP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and an implementation which uses the socket API of embOS/IP as well as an implementation which uses the zero-copy API of embOS/IP.

IANA Private Enterprise Number (PEN)
For implementing SNMP in your own product you need to acquire a Private Enterprise Number (PEN) from the IANA. A PEN can be requested free of charge at the following location: http://pen.iana.org/pen/app
The PEN used in the samples (dec. 46410) is the PEN registered for SEGGER Microcontroller GmbH & Co. KG. This needs to be changed to your own PEN in your product and the content of the MIB is subject to change in the future.
34.4 SNMP backgrounds

The Simple Network Management Protocol is a standard protocol to manage IP based devices in a network. Typical usage is to monitor counters and status in network switches and other network equipment but can also be used for configuration read/write operations. The development of SNMP is coordinated by the IETF (Internet Engineering Task Force) with the widely used SNMPv2c inspired from several other sources. The current protocol version supported by the embOS/IP SNMP agent is v1 and v2c. The latest protocol version is v3.

The SNMP agent is the part that is implemented directly inside a device to fulfill requests like status information and configuration of the device.
34.4.1 Data organization in SNMP

SNMP data is organized in Management Information Base (MIB) blocks. The blocks itself are typically called MIB to keep it short, instead of “MIB blocks”. Each of these MIBs is organized in a tree like structure, able to have one parent and multiple childs. Every MIB has an unique Object Identifier (OID) on its level, making it possible to exactly walk the tree from top to bottom by following one MIB child OID after another.

A typical MIB tree for access to your own enterprise specific data is shown below. In this example the MIBs from the root node down to the SEGGER enterprise MIB are shown.

As can be seen from the MIB tree above, the SEGGER MIB is located at 1.3.6.1.4.1.46410. While everything above your own enterprise MIB is typically standardized, it is completely up to you what happens below your own MIB.
34.4.2 OID value, address and index

All locations and even items to access within the MIB tree are addressed by a so called “OID value”. The OID value consists of multiple OIDs addressing one specific item of a specific MIB in the tree. For this purpose in general the OID value consists of two parts:

- **Address**
- **Index**

The address part describes which MIB in the tree needs to be addressed. The index specifies the element of the MIB to access. Typically index .0 is used as scalar item which means that this is the main item of the addressed MIB. Typically this index is always present and serves the main feature of this MIB. For a hardware timer related MIB, index .0 could contain the current value of the timer. However it completely depends on the MIB which purpose any index serves.

Although typically the last OID is used as index, the index is not limited to one OID, making it impossible to know the address length if not known from any other source like a MIB description. As it completely depends upon the implementor of the MIB how the MIB and addresses below this MIB are used, indexes can even be multi dimensional:

This can be used for example to access a table by column and row index.
34.4.3 SNMP data types

The SNMP standard defines various generic data types throughout its versions and several pseudo data types. These pseudo data types use the same type IDs as the data type they base on and from the pure data stream they can not be differentiated from their original type. They are used in MIB descriptions to give several items a clean meaning and boundaries that the original type does not support. However both sides need to be aware that this type and its characteristics are required for this specific item.

The following is a list of data types currently supported by the SNMP agent and includes the most common native data types and some of their more generic pseudo data types that are typically in use in the wild.

34.4.3.1 Native data types

These data types are types that in general are available since SNMPv1. Some of them have been renamed for SNMPv2 but in general still serve the same functionality and newer types are constructed from them.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>0x02</td>
<td>Signed 32-bit integer.</td>
</tr>
<tr>
<td>OCTET STRING</td>
<td>0x04</td>
<td>U8 data array.</td>
</tr>
<tr>
<td>OBJECT IDENTIFIER</td>
<td>0x06</td>
<td>OID value used as address to access or value like a pointer.</td>
</tr>
<tr>
<td>IpAddress</td>
<td>0x40</td>
<td>U32 IP address.</td>
</tr>
<tr>
<td>Counter</td>
<td>0x41</td>
<td>Unsigned 32-bit value, non decreasing. Allowed to be used with SNMPv2. Using the SNMPv2 Counter32 is advised when working with SNMPv2 only.</td>
</tr>
<tr>
<td>Gauge</td>
<td>0x42</td>
<td>Unsigned 32-bit value. Only SNMPv1.</td>
</tr>
<tr>
<td>Gauge32</td>
<td>0x42</td>
<td>Unsigned 32-bit value. Only SNMPv2 and above. Can be considered an alias of Gauge as its own type as only present for SNMPv2 and above.</td>
</tr>
<tr>
<td>TimeTicks</td>
<td>0x43</td>
<td>Unsigned 32-bit value, non decreasing.</td>
</tr>
<tr>
<td>Opaque</td>
<td>0x44</td>
<td>The Opaque type is typically only used in SMIPv1 MIBs and can be used to extend the list of existing types with encapsulated and constructed types. The downside is that these types are not generic and can therefore not be understood by anyone else if they do not know the exact content encapsulated. The status with SNMPv2 for this type is deprecated but allowed.</td>
</tr>
</tbody>
</table>
### 34.4.3.2 Constructed and new data types

These data types are either newer versions of an old SNMPv1 data type and have been renamed to be more precise in their name or they are technically the same as other native data types but respect other boundaries in their values. For all types the same rule applies: Both, manager and agent need to be aware of how to handle this data type and its characteristics.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer32</td>
<td>0x02</td>
<td>Signed 32-bit integer. SNMPv2 version of the INTEGER data type.</td>
</tr>
<tr>
<td>BITS</td>
<td>0x04</td>
<td>Array of bit values sent in an U8 data array. Basically the same as the OCTET STRING data type.</td>
</tr>
<tr>
<td>Counter32</td>
<td>0x41</td>
<td>Unsigned 32-bit value, non decreasing. SNMPv2 version of Counter. Only supported by SNMPv2 and above.</td>
</tr>
<tr>
<td>Unsigned32</td>
<td>0x42</td>
<td>Unsigned 32-bit value. Only SNMPv2. Basically the same as the Gauge data type.</td>
</tr>
</tbody>
</table>

#### Opaque based data types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Counter64</td>
<td>0x46</td>
<td>Unsigned 64-bit value, non decreasing. Implemented using the Opaque type.</td>
</tr>
<tr>
<td>Float</td>
<td>0x78</td>
<td>IEEE 754 single-precision float. Implemented using the Opaque type.</td>
</tr>
<tr>
<td>Double</td>
<td>0x79</td>
<td>IEEE 754 double-precision float. Implemented using the Opaque type.</td>
</tr>
<tr>
<td>Integer64</td>
<td>0x7A</td>
<td>Signed 64-bit integer. Implemented using the Opaque type.</td>
</tr>
<tr>
<td>Unsigned64</td>
<td>0x7B</td>
<td>Unsigned 64-bit value. Implemented using the Opaque type.</td>
</tr>
</tbody>
</table>
34.4.4 Participants in an SNMP environment

In an SNMP environment there are typically at least an SNMP agent serving requests and a manager sending requests to the agent and waiting a response sent back. The only exception to this behavior is a TRAP (SNMPv1/SNMPv2c) message that is being sent unrequested from agent to manager to signal an event has happened. While for a TRAP message no answer is sent back from a manager to the agent, SNMPv2c introduces the INFORM (for SNMPv2c) message that awaits an acknowledge sent back from manager to agent.

While a single manager can operate with several agents alone, sometimes it is more efficient to use a master agent in between. The job of the master agent is to collect information from several agents and to provide a single communication partner for the manager to operate with. A manager can operate with multiple single agents and master agents at the same time.

The following picture shows the topology between a manager, one master agent and multiple agents:

[Diagram showing the topology with Manager, Master Agent, and multiple Agents with TRAP, INFORM, and INFORM ACK messages]
### 34.4.5 Differences between SNMP versions

Today there are three SNMP versions that are used in products and can be considered as standards when talking about SNMP.

#### SNMPv1

The initial version of the protocol starting from 1988 supports the following message types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>get-request</td>
<td>Requests one or more values from specific OID values.</td>
</tr>
<tr>
<td>getnext-request</td>
<td>Requests the next available OID value after the start OID value sent with the getnext-request. Multiple requests can be sent in one getnext-request message.</td>
</tr>
<tr>
<td>get-response</td>
<td>Responses sent back upon any request message received.</td>
</tr>
<tr>
<td>set-request</td>
<td>Sets one or more values for specific OID values.</td>
</tr>
<tr>
<td>TRAPv1</td>
<td>Unrequested message sent from agent to one or more managers. Does not check for reception of the message.</td>
</tr>
</tbody>
</table>

Although criticized for its poor security, only using a community string that is transmitted in cleartext SNMPv1 became the de facto standard for device management in a network.

#### SNMPv2c

SNMPv2 has been designed with better security in mind and supports the following new message types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getbulk-request</td>
<td>Used for sending one or multiple getnext-requests to retrieve a large amount of data.</td>
</tr>
<tr>
<td>TRAPv2</td>
<td>Unrequested message sent from agent to one or more managers. Does not check for reception of the message. Same as a TRAPv1 message but does not use its own message format anymore but the standard SNMP PDU message format.</td>
</tr>
<tr>
<td>INFORM</td>
<td>Unrequested message sent from agent to one or more managers. Awaits an acknowledge sent back from the manager and is re-transmitted if the acknowledge is not received.</td>
</tr>
</tbody>
</table>

The original SNMPv2 introduced a new security system which was seen by many as too complex and therefore not widely accepted. The de facto standard later became SNMPv2c which stand for SNMPv2 with community based security which works the same as in SNMPv1 by using a clear-type community string. SNMPv2c therefore combines the simple to use and implement community based security model with the improved performance and new message types introduced with SNMPv2.
34.4.6 SNMP communication basics

SNMP is a request and response protocol. This means that always a manager sends a request to an agent and the agent sends back a response to the manager. The only exception from this concept is for TRAP and INFORM messages where the agent sends a notification about an event that has happened at the agent to a defined list of one or more managers.

The encoding used in SNMP messages is a binary encoding, so the data cannot be read clear-type. An SNMP message consists of several nested elements as can be seen in the following picture:
34.4.7 SNMP agent return codes

The embOS/IP SNMP agent API distinguishes two types of return codes.

• Generic SNMP protocol error codes
• embOS/IP SNMP agent API error codes

Both types might be returned by the embOS/IP SNMP agent API depending on if an internal error in the API or an SNMP protocol error has occurred.

Generic SNMP protocol return codes

These return codes are generic for the SNMP protocol and are sent in an SNMP message. Only these return codes are expected to be used in a MIB callback registered with the embOS/IP SNMP agent API.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_SNMP_OK</td>
<td>0</td>
<td>Everything O.K.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_TOO_BIG</td>
<td>1</td>
<td>Either the request received was too big to parse or the response to send does not fit into one SNMP message.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_NO_SUCH_NAME</td>
<td>2</td>
<td>The OID value to access does not exist.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_BAD_VALUE</td>
<td>3</td>
<td>Syntax or value error.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_GENERIC</td>
<td>5</td>
<td>Generic error, not further specified.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_NO_ACCESS</td>
<td>6</td>
<td>The OID value to access is not available. Might be due to not being visible for the supplied community string.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_WRONG_TYPE</td>
<td>7</td>
<td>Typically sent back for a set-request with a non-matching type field for a value to set. For example if an INTEGER is expected but the set-request contains an Unsigned32 value to set.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_NO_CREATION</td>
<td>11</td>
<td>The OID value to access in a set-request does not exist and the agent is unable to create it.</td>
</tr>
<tr>
<td>IP_SNMP_ERR_AUTH</td>
<td>16</td>
<td>No access to this OID value, e.g. wrong community string.</td>
</tr>
</tbody>
</table>

embOS/IP SNMP agent API return codes

These return codes are used by the embOS/IP SNMP agent API to return the result of internal processes such as parsing results and generating responses.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_SNMP_AGENT_OK</td>
<td>0</td>
<td>Everything O.K.</td>
</tr>
<tr>
<td>IP_SNMP_AGENT_ERR_MISC</td>
<td>-1</td>
<td>Generic error, not further specified.</td>
</tr>
<tr>
<td>IP_SNMP_AGENT_ERR_UNSUPPORTED_VERSION</td>
<td>-2</td>
<td>A message has been received with an unsupported protocol version.</td>
</tr>
<tr>
<td>IP_SNMP_AGENT_ERR_AUTH</td>
<td>-3</td>
<td>Wrong community string received in request. Requested action is not allowed.</td>
</tr>
<tr>
<td>IP_SNMP_AGENT_ERR_MALFORMED_MESSAGE</td>
<td>-4</td>
<td>Error while parsing a received message.</td>
</tr>
</tbody>
</table>
34.5 Using the SNMP agent samples

Ready to use examples for Microsoft Windows and embOS/IP are supplied. If you use another UDP/IP stack, the samples have to be adapted.

The supplied sample application OS_IP_SNMP_Agent.c and OS_IP_SNMP_Agent_ZeroCopy.c basically do the same. They open the UDP ports 161 and 162 to listen for incoming SNMP messages. Port 161 is the default port for SNMP requests and is mandatory for SNMP communication. Port 162 is the default port for sending SNMP TRAP messages and receiving SNMP INFORM messages and the acknowledge sent back. Therefore in an SNMP agent if no INFORM messages shall be sent at all, listening on this port is optional.

The two samples supplied for embOS/IP do the same for the SNMP agent. However they differ in the way they are using the UDP/IP stack used for communication.

34.5.1 OS_IP_SNMP_Agent.c

This sample uses the standard BSD socket interface and can be easily ported to any other BSD socket compatible UDP/IP stack. It requires static or allocated buffers for most of the SNMP processing and typically causes several data copy operations in the IP stack itself due to the nature of the socket interface.

SNMP messages received need to be copied into a local buffer that can then be supplied to the SNMP agent API for message parsing. A second local buffer needs to be supplied to store the response to send back. The response then needs to be copied into the socket buffer by the IP stack for the UDP message to send.

Sending a TRAP or INFORM message again requires several local buffers to form and send/receive messages.

34.5.2 OS_IP_SNMP_Agent_ZeroCopy.c

This sample uses the embOS/IP UDP zero-copy API to handle SNMP messages in a very effective way without unnecessary copy operations in the receive and send paths.

In addition to saving almost all local buffers that are required for SNMP message processing, the SNMP agent can be handled easily without any task at all which saves task stack as well.

Received SNMP messages are directly passed to the SNMP agent together with their packet descriptor to the message parser routines without the need to copy their UDP payload into another buffer. The same applies for the response output. An allocated packet buffer can be passed completely to the parser routines and the response is stored directly in the packet buffer. This way the response can be passed to embOS/IP for sending without first having to copy the payload into another buffer.

As the packet buffers are pre-allocated in embOS/IP upon initialization and the memory is not freed internally, this also prevents memory fragmentation while providing a flexible way to allocate memory for receiving and sending SNMP messages.

34.5.3 Using the Windows SNMP agent sample

If you have MS Visual C++ 6.00 or any later version available, you will be able to work with a Windows sample project using the embOS/IP SNMP agent. If you do not have the Microsoft compiler, a precompiled executable of the SNMP agent is also supplied.

Building the sample program

Open the workspace SNMP_Agent.dsw with MS Visual Studio (for example, double-clicking it). There is no further configuration necessary. You should be able to build the application without any error or warning message.

The server uses the IP address of the host PC on which it runs.
34.5.4 Features of the SNMP agent sample application

The sample as shipped is configured for operating/simulating a system with 8 LEDs.

A base MIB tree is added providing a sample implementation of a custom MIB node at the SEGGER enterprise OID value "1.3.6.1.4.1.46410". This evaluates to the following OID path in clear text: "iso(1).org(3).dod(6).internet(1).private(4).enterprise(1).ENCODED(46410)".

The ID “46410” is the Private Enterprise Number (PEN) registered for SEGGER. All OIDs above the value “127” have to be BER encoded. You will need to apply for your own PEN with the IANA to avoid collisions with other enterprises. You are only allowed to design a product with SNMP with your own PEN. Registering for your own PEN is free of charge. For more information please refer to SNMP agent requirements on page 894.

The sample provided is able to retrieve and set the status of 8 LEDs. A callback registered to the OID "iso(1).org(3).dod(6).internet(1).private(4).enterprise(1).ENCODED(46410)" handles all further OIDs beneath the OID of the MIB with the callback. The LED is indexed with a single dimensional index. The following indexes are supported:

- .0: Read only. Status of all LEDs in one single byte. Bit 0 set in this byte means that the first LED is on. Bit 1 set in this byte means that the second LED is on.
- .1 to .8: Read/Write. The status of the LEDs with index 0 to 7 can be retrieved/set using the corresponding index. For a set-request a value of type INTEGER is expected. A value of 0 clears the LED while any other value sets the LED.

After the initialization of the SNMP agent the sample application sends a coldBoot trap with a bogus Varbind to the hosts configured in the configuration area at the top of the sample application. This is typically done to notify managers of the availability of this agent.

The sample is configured to use two community strings for authentication:

- "public": Read only access.
- "Segger": Read/write access.
### 34.5.5 Testing the SNMP agent sample application

For an easy test of the SNMP protocol the de facto standard SNMP tool set Net-SNMP can be used. It can be downloaded from the following location:

[http://www.net-snmp.org](http://www.net-snmp.org)

The following command line examples show how the SNMP functionality of the sample can be tested.

**Clear the first LED**

```
snmpset -v2c -c Segger <AgentIP> 1.3.6.1.4.1.46410.1 i 0
```

```
iso.3.6.1.4.1.46410.1 = INTEGER: 0
```

**Set the second LED**

```
snmpset -v2c -c Segger <AgentIP> 1.3.6.1.4.1.46410.2 i 1
```

```
iso.3.6.1.4.1.46410.2 = INTEGER: 1
```

**Retrieve the status of all 8 LEDs in one byte**

```
snmpget -v2c -c public <AgentIP> 1.3.6.1.4.1.46410.0
```

```
iso.3.6.1.4.1.46410.0 = INTEGER: 2
```

First LED (bit 0) is cleared, second LED (bit 1) is set, all other LEDs are cleared.

**Get the next available value in MIB tree.**

Retrieve the first element available starting from “iso(1).org(3).dod(6)”.

```
snmpgetnext -v2c -c public <AgentIP> 1.3.6
```

```
iso.3.6.1.4.1.46410.0 = INTEGER: 2
```

Returns the next available element in the MIB tree which is the the current LED status.

**HBody Get the LED in single byte and all single LED status in one request.**

Retrieve the LED status and output up to 9 elements after the LED status index.

```
snmpbulkget -v2c -c public -Cn1 -Cr9 <AgentIP> 1.3.6.1.4.1.46410 1.3.6.1.4.1.46410.0
```

```
...  
iso.3.6.1.4.1.46410.0 = INTEGER: 2  
iso.3.6.1.4.1.46410.1 = INTEGER: 0  
iso.3.6.1.4.1.46410.2 = INTEGER: 1  
iso.3.6.1.4.1.46410.3 = INTEGER: 0  
iso.3.6.1.4.1.46410.4 = INTEGER: 0  
iso.3.6.1.4.1.46410.5 = INTEGER: 0  
iso.3.6.1.4.1.46410.6 = INTEGER: 0  
iso.3.6.1.4.1.46410.7 = INTEGER: 0  
iso.3.6.1.4.1.46410.8 = INTEGER: 0  
iso.3.6.1.4.1.46410.8 = No more variables left in this MIB View (It is past the end of the MIB tree)
```

A getbulk-request is a combination of multiple getnext-requests. In this example “-Cn1” defines that the first OID value of all OIDs given as parameter shall only retrieve one value. “-Cr9” would mean that the two first OID values given shall return only one value each. For all following OID values “-Cr9” defines that up to 9 values shall be retrieved for each OID value. In this example only one OID value follows the single value OID value(s) and as
only the index .0 to .8 is available in the sample and we start at .0 with a getnext-request, this retrieves the values for the indexes .1 to .8 with an exception that we reached the end of the MIB tree searching for the next element at index .8.

**Testing TRAP and INFORM messages**

The sample sends a `coldBoot` TRAP or INFORM message depending on the configuration set in the sample to selected SNMP managers.

For testing TRAP and INFORM messages you will need either a fully functional SNMP manager or any other software that is able to open the trap UDP port (typically 162) and listens for TRAP or INFORM messages to be sent by an agent.

One simple software to test TRAP and INFORM messages is the free MIB browser available from ManageEngine that can be downloaded from the following location: [https://www.manageengine.com/products/mibbrowser-free-tool/trap-receiver.html](https://www.manageengine.com/products/mibbrowser-free-tool/trap-receiver.html)

It does not only provide a GUI driven SNMP manager to test the agent but also comes with a TRAP browser to collect and visualize TRAP and INFORM messages sent by the embOS/IP SNMP agent. You will need to configure the IP address of the host running the TRAP browser in the SNMP agent sample.
34.6 The MIB callback

To each MIB of the embos/IP SNMP agent MIB tree, a callback for handling sub OIDs and indexes can be registered. For each OID value to access the SNMP agent will search for the first available OID of a parent MIB and execute the callback assigned to it. This callback will then be given information about the OID value to access. It then needs to parse the information available in the received message and form a response if no error shall be sent back.

As for an SNMP agent internally getbulk-requests are handled the same way as getnext-requests, the SNMP agent will use getnext-requests for the callback to fulfill, even if it originally was a getbulk-request that has been received.

Therefore the three types that shall be handled by a MIB callback are:

- set-request
- get-request
- getnext-request

A sample implementation can be found in the provided samples in the function _SNMP_Sample_cb():

```c
/*********************************************************************
* _SNMP_Sample_cb()
* Function description
* Callback handler that can be assign to one or more MIBs.
* Parameters
* pContext : Context for the current message and response.
* pUserContext: User specific context passed to the process message API.
* pMIB : Pointer to the MIB that is currently accessed.
* MIBLen : Length of the MIB that is currently accessed.
* pIndex : Pointer to the encoded index of the OID.
* IndexLen : Length of the encoded index in bytes.
* RequestType : IP_SNMP_PDU_SET_REQUEST or
* IP_SNMP_PDU_GET_REQUEST or
* IP_SNMP_PDU_TYPE_GET_NEXT_REQUEST .
* VarType : Type of variable that waits to be parsed for input data.
* Only valid if RequestType is IP_SNMP_PDU_SET_REQUEST .
* Return value
* Everything O.K. : IP_SNMP_OK
* In case of an error: IP_SNMP_ERR_*
* Additional information
* `pIndex might point to more than one index OID value e.g. when
* using multi dimensional arrays. In any case the index should
* be decoded before it is used to make sure values above 127
* are correctly used.
* Parameters of a set-request need to be stored back with their new value.
* The memory that pMIB and pIndex point to might be reused by store
* functions. If the data stored at their location is important you
* have to save them locally on your own. It is advised to do all
* checks at the beginning of the callback so you do not rely on these
* parameters while or after you use store functions.
*/
static int _SNMP_Sample_cb (       IP_SNMP_AGENT_CONTEXT * pContext ,
void * pUserContext ,
const U8 * pMIB ,
U32 MIBLen ,
const U8 * pIndex ,
U32 IndexLen ,
U8 RequestType ,
U8 VarType ) {
    I32 OnOff ;
    U32 Index ;
    U32 NumBytesDecoded ;
    U8 LEDMask ;

    (void)pUserContext; // Context passed through the whole SNMP API by
    // the application.
```
(void)pMIB;     // OID part with the address of the MIB found.
(void)MIBLen;   // Length of the MIB OID.

LEDMask         =  0;
NumBytesDecoded = IndexLen;

    return IP_SNMP_ERR_GENERIC;
}
if (RequestType == IP_SNMP_PDU_TYPE_GET_NEXT_REQUEST) {    // Handle getnext-request.
    // A getnext-request has to provide the next indexed item after the
    // one addressed. As for this sample we expect to have only a one
    // dimensional index this is simply incrementing the read index by one.
    // For a getnext-request the callback has to store the OID value of the new item
    // as well.
    // In general the callback has the following options how to react:
    // 1) The callback is able to store the next item after the given index:
       // The callback has to store the the OID and the value of the next item.
    // 2) The callback is NOT able to store the next item after the given index:
       // The callback has to store an NA exception or to report an
       // IP_SNMP_ERR_NO_CREATION error.
    // Index++;
    }    // Do some checks.
    //
    if ((Index > 8) ||
        (IndexLen > NumBytesDecoded)) {    // We expect to have only one index, if
        // there are more index bytes to parse this
        // means an error (trying to access .x.y
        // where only .x is available).

            } else {
CHAPTER 34

The MIB callback

```c
_LEDState &= (LEDMask ^ 255);
BSP_ClrLED(Index - 1);
}
if (IP_SNMP_AGENT_StoreInteger(pContext, OnOff) != 0) {
    return IP_SNMP_ERR_TOO_BIG;
}
} else { // Handle get-request.
    if (RequestType == IP_SNMP_PDU_TYPE_GET_NEXT_REQUEST) {
        // Store OID of "next" item returned if this is for a getnext-request.
        // The value will be stored by the following code in case of a getnext-
        // and a get-request.
        //
        if (IP_SNMP_AGENT_StoreCurrentMibOidAndIndex(pContext, pContext, 1, Index) != 0) {
            return IP_SNMP_ERR_TOO_BIG;
        }
    }
    // Get LED state based on index:
    // Index 0: Get LED state for all 8 possible LEDs in one byte.
    // Other : Get LED state for one specific LED in one byte.
    //
    if (Index == 0) {
        if (IP_SNMP_AGENT_StoreInteger(pContext, _LEDState) != 0) {
            return IP_SNMP_ERR_TOO_BIG;
        }
    } else { // Return status of one LED.
        //
        if ((LEDState & LEDMask) != 0) {
            OnOff = 1;
        } else {
            OnOff = 0;
        }
        if (IP_SNMP_AGENT_StoreInteger(pContext, OnOff) != 0) {
            return IP_SNMP_ERR_TOO_BIG;
        }
    }
}
return IP_SNMP_OK;
```
34.7 SNMP agent configuration

The embOS/IP SNMP agent can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

34.7.1 SNMP agent configuration macro types

The following types of configuration macros exist:

Binary switches "B"

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

Numerical values "N"

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

Alias "A"

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

Function replacements "F"

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

34.7.2 SNMP agent compile time configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>
| F    | IP_SNMP_AGENT_WARN | -- | Defines a function to output warnings. In debug configurations (DEBUG = 1) `IP_SNMP_AGENT_WARN` maps to `IP_Warnf_Application()`.
| F    | IP_SNMP_AGENT_LOG | -- | Defines a function to output logging messages. In debug configurations (DEBUG = 1) `IP_SNMP_AGENT_LOG` maps to `IP_Logf_Application()`.
| B    | IP_SNMP_AGENT_SUPPORT_PANIC_CHECK | Debug: 1 Release: 0 | Defines if upon a critical error the execution shall be halted.
| B    | IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES | 1 | Defines if 64-bit types like double and relatives like float are supported.
| N    | IP_SNMP_AGENT_WORK_BUFFER | 64 | Defines the size of the buffer used to do internal work like assembling OID values for further usage. |
### 34.8 API functions

<table>
<thead>
<tr>
<th>Function</th>

</table>
34.8.1 IP_SNMP_AGENT_AddCommunity()

Description

Adds a community string for access rights management.

Prototype

```c
void IP_SNMP_AGENT_AddCommunity(
    IP_SNMP_AGENT_COMMUNITY *  pCommunity,
    const char                     *  sCommunity,
    U32                       Len);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pCommunity</td>
<td>Pointer to IP_SNMP_AGENT_COMMUNITY memory block.</td>
</tr>
<tr>
<td>sCommunity</td>
<td>Community string to add.</td>
</tr>
<tr>
<td>Len</td>
<td>Length of the community string without termination.</td>
</tr>
</tbody>
</table>
34.8.2   IP_SNMP_AGENT_AddMIB()

Description
Adds a MIB to the tree.

Prototype

```c
int IP_SNMP_AGENT_AddMIB(const U8 * pParentOID, U32 Len, IP_SNMP_AGENT_MIB * pMIB, IP_SNMP_AGENT_pfMIB pf, U32 Id);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParentOID</td>
<td>Pointer to parent OID in MIB tree.</td>
</tr>
<tr>
<td>Len</td>
<td>Length of parent OID.</td>
</tr>
<tr>
<td>pMIB</td>
<td>Pointer to new MIB to add.</td>
</tr>
<tr>
<td>pf</td>
<td>Callback handler for this MIB.</td>
</tr>
<tr>
<td>Id</td>
<td>Actual identifier of the new OID.</td>
</tr>
</tbody>
</table>

Return value

- $= 0$  O.K.
- $≠ 0$  Error.
34.8.3  IP_SNMP_AGENT_AddInformResponseHook()

Description
Registers a hook that is called upon a state change of an INFORM item waiting for an ACK.

Prototype

void IP_SNMP_AGENT_AddInformResponseHook
(IP_SNMP_AGENT_HOOK_ON_INFORM_RESPONSE * pHook,
 IP_SNMP_AGENT_pfOnInformResponse pf);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pHook</td>
<td>Pointer to element of type IP_SNMP_AGENT_HOOK_ON_INFORM_RESPONSE.</td>
</tr>
<tr>
<td>pf</td>
<td>Function pointer to callback to hook in.</td>
</tr>
</tbody>
</table>
34.8.4  IP_SNMP_AGENT_CancelInform()

Description
Cancels an INFORM message that might be still in process of resending. Resources for this message can then be freed.

Prototype

```c
void IP_SNMP_AGENT_CancelInform
    (IP_SNMP_AGENT_TRAP_INFORM_CONTEXT * pTrapInformContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pTrapInformContext</td>
<td>Pointer to context of message sent.</td>
</tr>
</tbody>
</table>

Additional information
Canceling a message will not overwrite an already set status.
### 34.8.5 IP_SNMP_AGENT_CheckInformStatus()

**Description**

Retrieves the status of an INFORM message sent.

**Prototype**

```c
int IP_SNMP_AGENT_CheckInformStatus(IP_SNMP_AGENT_TRAP_INFORM_CONTEXT * pContext);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to INFORM context that has been used for sending.</td>
</tr>
</tbody>
</table>

**Return value**

Current status of the INFORM message:

- `IP_SNMP_AGENT_INFORM_STATUS_WAITING_FOR_ACK`
- `IP_SNMP_AGENT_INFORM_STATUS_ACK_RECEIVED`
- `IP_SNMP_AGENT_INFORM_STATUS_NACK_RECEIVED`
- `IP_SNMP_AGENT_INFORM_STATUS_CANCELED`
- `IP_SNMP_AGENT_INFORM_STATUS_TIMEOUT`
34.8.6 IP_SNMP_AGENT_DeInit()

Description
Deinitializes the SNMP agent.

Prototype
void IP_SNMP_AGENT_DeInit(void);

Additional information
All tasks and external resources that use the SNMP agent API need to be stopped before deinitialization.
34.8.7  IP_SNMP_AGENT_Exec()

Description
Executes management tasks.

Prototype

I32 IP_SNMP_AGENT_Exec(void);

Return value
Time [ms] until the next timeout runs out.

Additional information
Typically checks if it is time to resend an INFORM message for which we have not yet received an ACK. The return value describes how long a task calling this function can sleep before it should execute this function again to handle management functionality.
34.8.8  IP_SNMP_AGENT_GetMessageType()

Description
Retrieves the message type of the message in the given buffer.

Prototype

```c
int IP_SNMP_AGENT_GetMessageType(const U8 * pIn,
                                  U32   NumBytesIn,
                                  U8   * pType);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIn</td>
<td>Pointer to received SNMP message.</td>
</tr>
<tr>
<td>NumBytesIn</td>
<td>Length of received SNMP message.</td>
</tr>
<tr>
<td>pType</td>
<td>Pointer where to store the parsed PDU message type.</td>
</tr>
</tbody>
</table>

Return value

- `= 0`  O.K.
- `≠ 0`  Error.

Additional information

By checking the message type beforehand it is possible to use the same port for normal get-requests and INFORM handling by using this routine to distinguish which API is required to process the received message.
34.8.9  IP_SNMP_AGENT_Init()

**Description**

Initializes the SNMP agent.

**Prototype**

```c
void IP_SNMP_AGENT_Init(const IP_SNMP_AGENT_API * pAPI);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAPI</td>
<td>Pointer to SNMP agent API.</td>
</tr>
</tbody>
</table>
34.8.10 IP_SNMP_AGENT_PrepareTrapInform()

Description
Prepares a TRAP/INFORM message.

Prototype

```c
void IP_SNMP_AGENT_PrepareTrapInform
(       IP_SNMP_AGENT_CONTEXT *  pContext ,
void *  pUserContext ,
const U8 *  pEnterpriseOID ,
U32 EnterpriseOIDLen ,
const U8 *  pTrapOID ,
U32 TrapOIDLen ,
U8 *  pBuffer ,
U32 BufferSize ,
U32 AgentAddr );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pUserContext</td>
<td>User specific context passed to callbacks.</td>
</tr>
<tr>
<td>pEnterpriseOID</td>
<td>Pointer to enterprise OID sent in TRAP/INFORM.</td>
</tr>
<tr>
<td>EnterpriseOIDLen</td>
<td>Length of enterprise OID.</td>
</tr>
<tr>
<td>pTrapOID</td>
<td>Pointer to SMIv2 TRAP OID sent as source.</td>
</tr>
<tr>
<td>TrapOIDLen</td>
<td>Length of TRAP OID.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to buffer where to construct the Varbinds to send.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of the construct buffer.</td>
</tr>
<tr>
<td>AgentAddr</td>
<td>IP addr. of agent sending the traps. For IPv6 simply 0.</td>
</tr>
</tbody>
</table>

Additional information

This routine prepares the context so that by using store functions a custom VarbindList can be build. The message can then be sent either once or multiple times using this context with the send routine. For SNMPv1 and SNMPv2 TRAP/INFORM messages there are different information sent in them. What both share is that at least either the enterprise OID value or the TRAP OID value are included. The biggest difference is that SNMPv1 TRAPS did not have a location in the MIB tree and were a separate message type with its own message format that differs from all other SNMP messages. With SNMPv2 TRAPS now have a location inside the MIB tree.

For sending SNMPv1 and sending SNMPv2 messages there are different rules that apply but can be easily satisfied in your application by always providing both `pEnterpriseOID/EnterpriseOIDLen` and `pTrapOID/TrapOIDLen`. The information required for the specific SNMP version to send will be chosen automatically.

The SNMP agent API expects the TRAP OID value to be in SMIv2 form which means that the second to last OID is a zero. This is due to the fact that it is simpler to convert an SMIv2 OID value to SMIv1 than the other way round. For an SNMPv2 TRAP/INFORM the TRAP OID value is sent as is as no conversion is necessary. For sending an SNMPv1 TRAP the TRAP OID value needs to be converted.

For a specific SNMPv1 TRAP this means that the last OID of the TRAP OID value is written into the SpecificID field of the message and all OIDs before the second to last zero OID are used as the enterprise OID value. However there is one exception to this procedure:

For a generic SNMPv1 TRAP a special rule applies. As TRAPS are now mapped into the MIB tree as well there is a difference to their previous form of not having a location at all. Their SMIv2 form does not have the second to last zero OID and they are not directly converted...
from SMIv2 to SMIv1 TRAP OID values as others but instead are mapped to their previous
GenericIDs. In case of a generic SNMPv1 TRAP this means that the EnterpriseID is taken as
provided by pEnterpriseOID/EnterpriseOIDLen and the SMIv2 TRAP OID value provided
via pTrapOID/TrapOIDLen is replaced by the proper SMIv1 TRAP OID value.

The following table shows the list of defines available from the SNMP agent header file to
be used with pTrapOID / TrapOIDLen for sending SNMPv1 generic TRAPs:

<table>
<thead>
<tr>
<th>Define</th>
<th>SMIv2 OID</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_COLD_START</td>
<td>1.3.6.1.6.3.1.1.5.1</td>
</tr>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_WARM_START</td>
<td>1.3.6.1.6.3.1.1.5.2</td>
</tr>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_LINK_DOWN</td>
<td>1.3.6.1.6.3.1.1.5.3</td>
</tr>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_LINK_UP</td>
<td>1.3.6.1.6.3.1.1.5.4</td>
</tr>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_AUTHENTICATION_FAILURE</td>
<td>1.3.6.1.6.3.1.1.5.5</td>
</tr>
<tr>
<td>IP_SNMP_GENERIC_TRAP_OID_EGP_NEIGHBOR_LOSS</td>
<td>1.3.6.1.6.3.1.1.5.6</td>
</tr>
</tbody>
</table>
34.8.11 IP_SNMP_AGENT_ProcessInformResponse()

Description
Processes a response that has been received for a previously sent INFORM message.

Prototype

```c
int IP_SNMP_AGENT_ProcessInformResponse(const U8 * pIn,
                                         U32 NumBytesIn);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIn</td>
<td>Pointer to received SNMP message.</td>
</tr>
<tr>
<td>NumBytesIn</td>
<td>Length of received SNMP message.</td>
</tr>
</tbody>
</table>

Return value

- 0    O.K.
- ≠ 0  Error.
34.8.12 IP_SNMP_AGENT_ProcessRequest()

Description
Processes a received message and fills the output buffer with the response for sending back.

Prototype

```c
int IP_SNMP_AGENT_ProcessRequest (const U8 * pIn,
                                  U32 NumBytesIn,
                                  U8 * pOut,
                                  U32 NumBytesOut,
                                  void * pUserContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pIn</td>
<td>Pointer to received SNMP message.</td>
</tr>
<tr>
<td>NumBytesIn</td>
<td>Length of received SNMP message.</td>
</tr>
<tr>
<td>pOut</td>
<td>Pointer to output buffer to store the SNMP response.</td>
</tr>
<tr>
<td>NumBytesOut</td>
<td>Size of buffer for response.</td>
</tr>
<tr>
<td>pUserContext</td>
<td>User specific context passed to callbacks.</td>
</tr>
</tbody>
</table>

Return value

\[
\begin{array}{c|c}
\text{Value} & \text{Description} \\
\hline
> 0             & Length of response to send.                     \\
= 0             & No response to send.                            \\
< 0             & Error.                                          \\
\end{array}
\]
34.8.13 IP_SNMP_AGENT_SendTrapInform()

Description

Sends a TRAP/INFORM message.

Prototype

```c
int IP_SNMP_AGENT_SendTrapInform
(void                               *  pContext ,
     IP_SNMP_AGENT_CONTEXT             *  pVarbindContext ,
     IP_SNMP_AGENT_TRAP_INFORM_CONTEXT *  pTrapInformContext );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Send context, typically a socket.</td>
</tr>
<tr>
<td>pVarbindContext</td>
<td>Pointer to an SNMP agent context holding Varbinds to send.</td>
</tr>
<tr>
<td>pTrapInformContext</td>
<td>Pointer to context of message to send.</td>
</tr>
</tbody>
</table>

Return value

- **= 0**  (TRAP) O.K., pContext and pTrapInformContext can be freed.
- **< 0**  (TRAP) Error (buffer not big enough ?), pContext and pTrapInformContext can be freed.
- **= 1**  (INFORM) O.K., pContext and pTrapInformContext need to be preserved for further usage.
- **< 0**  (INFORM) Error (buffer not big enough ?), pContext and pTrapInformContext need to be preserved for further usage.

Additional information

An error while sending the first INFORM message might not mean that a resend can not succeed. This might happen if at the moment of sending the first message from this routine no send buffer is available. However in a resend a buffer might be available.

To be on the safe side if resources might be freed or not IP_SNMP_AGENT_CancelInform() should be called for the message in question. After this it is safe to free the resources.
34.8.14   IP_SNMP_AGENT_SetCommunityPerm()

Description
Sets permissions for a community profile.

Prototype

```c
void IP_SNMP_AGENT_SetCommunityPerm(IP_SNMP_AGENT_COMMUNITY * pCommunity,
                                    const IP_SNMP_AGENT_PERM * pPerm);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pCommunity</td>
<td>Pointer to IP_SNMP_AGENT_COMMUNITY memory block.</td>
</tr>
<tr>
<td>pPerm</td>
<td>Pointer to permissions table to use for this community.</td>
</tr>
</tbody>
</table>
34.8.15 IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetIetfMib2Interfaces()

**Description**
Adds the base MIBs iso(1).org(3).dod(6).internet(1).ietf(2).mib2(1).interfaces(2) to the tree.

**Prototype**

```c
int IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetIetfMib2Interfaces
    (const IP_SNMP_AGENT_MIB2_INTERFACES_API * pAPI);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAPI</td>
<td>Pointer to information and callback structure of type IP_SNMP_AGENT_MIB2_INTERFACES_API.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- ≠ 0: Error.
34.8.16  IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetIetfMib2System()

Description

Adds the base MIBs iso(1).org(3).dod(6).internet(1).ietf(2).mib2(1).system(1) to the tree.

Prototype

```c
int IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetIetfMib2System
(const IP_SNMP_AGENT_MIB2_SYSTEM_API * pAPI);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pAPI</td>
<td>Pointer to information and callback structure of type IP_SNMP_AGENT_MIB2_SYSTEM_API.</td>
</tr>
</tbody>
</table>

Return value

- 0  O.K.
- ≠ 0  Error.
34.8.17 IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetPrivateEnterprise()

Description
Adds the base MIBs iso(1).org(3).dod(6).internet(1).private(4).enterprise(1) to the tree.

Prototype

```
int IP_SNMP_AGENT_AddMIB_IsoOrgDodInternetPrivateEnterprise(void);
```

Return value

- 0 O.K.
- ≠ 0 Error.
34.8.18  IP_SNMP_AGENT_CloseVarbind()

Description
Closes a previously opened Varbind after an OID and value pair has been stored and inserts
the length into the Varbind header.

Prototype

```c
int IP_SNMP_AGENT_CloseVarbind(IP_SNMP_AGENT_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pContext</code></td>
<td>Pointer to an SNMP agent context.</td>
</tr>
</tbody>
</table>

Return value

- `= 0` O.K.
- `≠ 0` Error.
34.8.19  IP_SNMP_AGENT_OpenVarbind()

Description
Prepares a Varbind in the output buffer of the given context.

Prototype

```c
int IP_SNMP_AGENT_OpenVarbind(IP_SNMP_AGENT_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
≠ 0  Error (buffer not big enough ?).
### 34.8.20 IP_SNMP_AGENT_StoreBits()

#### Description
Stores a bitfield into an SNMP message.

#### Prototype
```c
int IP_SNMP_AGENT_StoreBits(       IP_SNMP_AGENTCONTEXT * pContext,
                                    const U8                    * pData,
                                    U32                     NumBytes);
```

#### Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to bitfield.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of bitfield in bytes.</td>
</tr>
</tbody>
</table>

#### Return value
- `= 0` O.K.
- `≠ 0` Error.
### 34.8.21 IP_SNMP_AGENT_StoreCounter()

**Description**

Stores a Counter into an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_StoreCounter(IP_SNMP_AGENT_CONTEXT * pContext, U32 v);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Counter to store.</td>
</tr>
</tbody>
</table>

**Return value**

- `= 0`  O.K.
- `≠ 0`  Error.
34.8.22  IP_SNMP_AGENT_StoreCounter32()

Description
Stores a Counter32 into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreCounter32(IP_SNMP_AGENT_CONTEXT * pContext,
                                  U32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Counter32 to store.</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
≠ 0  Error.
**34.8.23 IP_SNMP_AGENT_StoreCounter64()**

**Description**
Stores a Counter64 into an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_StoreCounter64 ( IP_SNMP_AGENT_CONTEXT * pContext,
                                  U64                     v );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Counter64 to store.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- ≠ 0: Error.

**Additional information**

Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1`. 
34.8.24 IP_SNMP_AGENT_StoreCurrentMibOidAndIndex()

Description
Stores the currently processed MIB OID into an output buffer of another or the same context and adds the given indexes to the output buffer as well.

Prototype

```c
int IP_SNMP_AGENT_StoreCurrentMibOidAndIndex ( IP_SNMP_AGENT_CONTEXT * pDstContext,
                                              IP_SNMP_AGENT_CONTEXT * pSrcContext,
                                              U32 NumIndexes,
                                              ...);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pDstContext</td>
<td>Pointer to an SNMP agent context to store the OID value.</td>
</tr>
<tr>
<td>pSrcContext</td>
<td>Pointer to an SNMP agent context from where to generate the OID value.</td>
</tr>
<tr>
<td>NumIndexes</td>
<td>Number of variable arguments passed to this function.</td>
</tr>
</tbody>
</table>

Return value

- = 0  O.K.
- ≠ 0  Error.
34.8.25  IP_SNMP_AGENT_StoreDouble()

Description
Stores a double-precision float into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreDouble(IP_SNMP_AGENT_CONTEXT * pContext,
                               double v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Double to store.</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
≠ 0  Error.

Additional information

A value of type double is expected to be presented in IEEE 754 form. This is true for all compilers following the C99 standard and typically even for almost all other compilers following older C-standards. An easy way to check this is to test that a variable of type float with value 1.0 is stored as `0x3FF00000` in memory. Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1`. 
34.8.26  IP_SNMP_AGENT_StoreFloat()

Description
Stores a single-precision float into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreFloat ( IP_SNMP_AGENT_CONTEXT * pContext,
                                float v );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Float to store.</td>
</tr>
</tbody>
</table>

Return value

= 0     O.K.
< 0     Error.

Additional information

A value of type float is expected to be presented in IEEE 754 form. This is true for all compilers following the C99 standard and typically even for almost all other compilers following older C-standards. An easy way to check this is to test that a variable of type float with value 1.0 is stored as `0x3F800000` in memory.
34.8.27 IP_SNMP_AGENT_StoreGauge()

Description
Stores an Gauge into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreGauge(IP_SNMP_AGENT_CONTEXT * pContext,
                              U32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Gauge to store.</td>
</tr>
</tbody>
</table>

Return value

- = 0     O.K.
- ≠ 0     Error.
34.8.28  IP_SNMP_AGENT_StoreGauge32()

Description
Stores an Gauge32 into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreGauge32 (IP_SNMP_AGENT_CONTEXT * pContext,
                                 U32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Gauge32 to store.</td>
</tr>
</tbody>
</table>

Return value

= 0     O.K.
≠ 0     Error.
34.8.29  IP_SNMP_AGGENT_StoreInstanceNA()

Description
Stores a Varbind exception into an SNMP message if an instance (index) addressed is not available.

Prototype

```c
int IP_SNMP_AGENT_StoreInstanceNA ( IP_SNMP_AGENT_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
</tbody>
</table>

Return value

- 0  O.K.
- ≠ 0 Error.
34.8.30  IP_SNMP_AGENT_StoreInteger()

Description
Stores an INTEGER into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreInteger(IP_SNMP_AGENT_CONTEXT * pContext, I32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>INTEGER to store.</td>
</tr>
</tbody>
</table>

Return value

= 0    O.K.
≠ 0    Error.
34.8.31 IP_SNMP_AGENT_StoreInteger32()

Description
Stores an INTEGER32 into an SNMP message.

Prototype

```
int IP_SNMP_AGENT_StoreInteger32 (IP_SNMP_AGENT_CONTEXT * pContext,
                                  I32 v);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>INTEGER32 to store.</td>
</tr>
</tbody>
</table>

Return value

- = 0   O.K.
- ≠ 0   Error.
34.8.32 IP_SNMP_AGENT_StoreInteger64()

Description
Stores an Integer64 into an SNMP message.

Prototype

\[
\text{int IP_SNMP_AGENT_StoreInteger64}(\text{IP_SNMP_AGENT_CONTEXT} * \text{pContext}, \\
\quad \text{I64 } \text{v});
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Integer64 to store.</td>
</tr>
</tbody>
</table>

Return value

\[
\begin{align*}
= 0 & \quad \text{O.K.} \\
\ne 0 & \quad \text{Error.}
\end{align*}
\]

Additional information

Can only be used when IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1.
34.8.33  IP_SNMP_AGENT_StoreIpAddress()

Description
Stores an IpAddress into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreIpAddress(IP_SNMP_AGENT_CONTEXT * pContext,
U32           IpAddress);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>IpAddress</td>
<td>IPv4 addr. as U32 in host order to store.</td>
</tr>
</tbody>
</table>

Return value

- = 0      O.K.
- ≠ 0      Error.
34.8.34  IP_SNMP_AGENT_StoreOctetString()

Description
Stores an octet string into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreOctetString(       IP_SNMP_AGENT_CONTEXT * pContext,
                                          const U8                    * pData,
                                          U32                     NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to octet string to store.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Length of octet string.</td>
</tr>
</tbody>
</table>

Return value

- = 0    O.K.
- ≠ 0    Error.
34.8.35   IP_SNMP_AGENT_StoreOID()

Description
Stores an OID into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreOID(       IP_SNMP_AGENT_CONTEXT *  pContext,
                                 const  U8                    *  pOIDBytes,
                                 U32                     OIDLen,
                                 U32                     MIBLen,
                                 U8                      IsValue);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pOIDBytes</td>
<td>Pointer to OID value.</td>
</tr>
<tr>
<td>OIDLen</td>
<td>Length of OID value.</td>
</tr>
<tr>
<td>MIBLen</td>
<td>Length of OID value that is part of the MIB.</td>
</tr>
<tr>
<td>IsValue</td>
<td>0: This is the OID value for which the result is sent.</td>
</tr>
<tr>
<td></td>
<td>1: This is a value field that contains an OID value.</td>
</tr>
</tbody>
</table>

Return value

- 0: O.K.
- ≠ 0: Error.
34.8.36  IP_SNMP_AGENT_StoreOpaque()

Description
Stores an Opaque into an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_StoreOpaque(
    IP_SNMP_AGENT_CONTEXT * pContext,
    const U8 * pData,
    U32 NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to Opaque data to store.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Size of Opaque data.</td>
</tr>
</tbody>
</table>

Return value

= 0   O.K.
≠ 0   Error.

Additional information

As an Opaque is a complex type and the content can be anything this function provides only the Opaque type field and the length field. All other content like the type inside the Opaque and the value itself has to be provided by the application.
### 34.8.37 IP_SNMP_AGENT_StoreTimeTicks()

**Description**
Stores a 32-bit TimeTick into an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_StoreTimeTicks ( IP_SNMP_AGENT_CONTEXT * pContext ,
                                  U32                     v );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>TimeTicks to store.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- ≠ 0: Error.
34.8.38  IP_SNMP_AGENT_StoreUnsigned32()

Description
Stores an Unsigned32 into an SNMP message.

Prototype

\[
\text{int IP_SNMP_AGENT_StoreUnsigned32(IP_SNMP_AGENT_CONTEXT * pContext, U32 v);}\
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Unsigned32 to store.</td>
</tr>
</tbody>
</table>

Return value

\[
\begin{align*}
\text{=} & \quad \text{O.K.} \\
\ne & \quad \text{Error.}
\end{align*}
\]
34.8.39  IP_SNMP_AGENT_StoreUnsigned64()

Description
Stores an Unsigned64 into an SNMP message.

Prototype

```c
int  IP_SNMP_AGENT_StoreUnsigned64 ( IP_SNMP_AGENT_CONTEXT *  pContext ,
                                  U64                     v );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>v</td>
<td>Unsigned64 to store.</td>
</tr>
</tbody>
</table>

Return value

- 0   O.K.
- ≠ 0   Error.

Additional information

Can only be used when IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1.
34.8.40  IP_SNMP_AGENT_ParseBits()

Description
 Parses an bitfield out of an SNMP message.

Prototype

```
int IP_SNMP_AGENT_ParseBits(       IP_SNMP_AGENT_CONTEXT * pContext,
        const U8 ** ppData,
        U32 * pLen);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>ppData</td>
<td>Pointer where to store the pointer to the data in the message.</td>
</tr>
<tr>
<td>pLen</td>
<td>Pointer where to store the data len.</td>
</tr>
</tbody>
</table>

Return value

= 0   O.K.
≠ 0   Error.

Additional information

This function expects that the type field has not been eaten out of the buffer.
### 34.8.41 IP_SNMP_AGENT_ParseCounter()

**Description**

Parses a Counter field out of an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_ParseCounter ( IP_SNMP_AGENT_CONTEXT * pContext,
                                U32                   * pCounter );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pCounter</td>
<td>Pointer where to store the parsed Counter.</td>
</tr>
</tbody>
</table>

**Return value**

- 0: O.K.
- ≠ 0: Error.

**Additional information**

By design a Counter is a 32-bit unsigned value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
34.8.42  IP_SNMP_AGENT_ParseCounter32()

Description
Parses a Counter32 field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseCounter32 ( IP_SNMP_AGENT_CONTEXT * pContext,
                                   U32                   * pCounter32 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pCounter32</td>
<td>Pointer where to store the parsed Counter32.</td>
</tr>
</tbody>
</table>

Return value

- 0  O.K.
- ≠ 0  Error.

Additional information

By design a Counter32 is a 32-bit unsigned value which does not mean that always 4 bytes are used in a message.

This function expects that the type field has not been eaten out of the buffer.
34.8.43  IP_SNMP_AGENT_ParseCounter64()

Description
Parses a Counter64 field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseCounter64(IP_SNMP_AGENT_CONTEXT * pContext,
                                  U64 * pCounter64);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pCounter64</td>
<td>Pointer where to store the parsed Counter64.</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
≠ 0  Error.

Additional information

By design a Counter64 is a 64-bit unsigned value which does not mean that always 8 bytes are used in a message.

This function expects that the type field has not been eaten out of the buffer.

Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1`. 
34.8.44 IP_SNMP_AGENT_ParseDouble()

Description
Parses a double field out of an SNMP message.

Prototype

```
int IP_SNMP_AGENT_ParseDouble(IP_SNMP_AGENT_CONTEXT * pContext,
                               double * pDouble);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pDouble</td>
<td>Pointer where to store the parsed double.</td>
</tr>
</tbody>
</table>

Return value

- = 0 O.K.
- ≠ 0 Error.

Additional information

A value of type double is expected to be presented in IEEE 754 form. This is true for all compilers following the C99 standard and typically even for almost all other compilers following older C-standards.

An easy way to check this is to test that a variable of type double with value 1.0 is stored as `0x3FF0000000000000` in memory. This function expects that the type field has not been eaten out of the buffer.

Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1`. 
34.8.45 IP_SNMP_AGENT_ParseFloat()

Description
Parses a float field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseFloat ( IP_SNMP_AGENT_CONTEXT * pContext,
                              float                  * pFloat );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pFloat</td>
<td>Pointer where to store the parsed float.</td>
</tr>
</tbody>
</table>

Return value

- 0 O.K.
- ≠ 0 Error.

Additional information

A value of type float is expected to be presented in IEEE 754 form. This is true for all compilers following the C99 standard and typically even for almost all other compilers following older C-standards.

An easy way to check this is to test that a variable of type float with value 1.0 is stored as 0x3F800000 in memory. This function expects that the type field has not been eaten out of the buffer.
### 34.8.46 IP_SNMP_AGENT_ParseGauge()

**Description**

Parses an Gauge field out of an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_ParseGauge (IP_SNMP_AGENT_CONTEXT * pContext,
                               U32                   * pUnsigned32);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pUnsigned32</td>
<td>Pointer where to store the parsed Gauge.</td>
</tr>
</tbody>
</table>

**Return value**

- = 0    O.K.
- ≠ 0    Error.

**Additional information**

By design an gauge is a 32-bit unsigned value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
34.8.47 IP_SNMP_AGENT_ParseGauge32()

Description
Parses an Gauge32 field out of an SNMP message.

Prototype

```
int IP_SNMP_AGENT_ParseGauge32 ( IP_SNMP_AGENT_CONTEXT * pContext,
                                 U32                   * pUnsigned32 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pUnsigned32</td>
<td>Pointer where to store the parsed Gauge32.</td>
</tr>
</tbody>
</table>

Return value

- 0  O.K.
- ≠ 0  Error.

Additional information

By design an Gauge32 is a 32-bit unsigned value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
**34.8.48 IP_SNMP_AGENT_ParseInteger()**

**Description**
Parses an INTEGER field out of an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_ParseInteger ( IP_SNMP_AGENT_CONTEXT * pContext,
                                I32                   * pInteger );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pInteger</td>
<td>Pointer where to store the parsed INTEGER.</td>
</tr>
</tbody>
</table>

**Return value**

- `= 0`  O.K.
- `≠ 0`  Error.

**Additional information**

By design an INTEGER is a 32-bit signed value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
34.8.49 IP_SNMP_AGENT_ParseInteger32()

Description
Parses an INTEGER32 field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseInteger32 ( IP_SNMP_AGENT_CONTEXT * pContext,
                                  I32                   * pInteger32 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pInteger32</td>
<td>Pointer where to store the parsed INTEGER32.</td>
</tr>
</tbody>
</table>

Return value

= 0     O.K.
≠ 0     Error.

Additional information

By design an INTEGER32 is a 32-bit signed value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
34.8.50 IP_SNMP_AGENT_ParseInteger64()

**Description**

Parses an Integer64 field out of an SNMP message.

**Prototype**

```c
int IP_SNMP_AGENT_ParseInteger64(IP_SNMP_AGENT_CONTEXT * pContext,
                                  I64 * pInteger64);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pInteger64</td>
<td>Pointer where to store the parsed Integer64.</td>
</tr>
</tbody>
</table>

**Return value**

- = 0  O.K.
- ≠ 0  Error.

**Additional information**

By design an Integer64 is a 64-bit signed value which does not mean that always 8 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.

Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1`. 
34.8.51 IP_SNMP_AGENT_ParseIpAddress()

Description
Parses an IpAddr field (IPv4) out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseIpAddress(IP_SNMP_AGENT_CONTEXT * pContext,
                                  U32 * pIpAddress);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pIpAddress</td>
<td>Pointer where to store the parsed IpAddr. The IP addr. stored as U32 in host order.</td>
</tr>
</tbody>
</table>

Return value

- **0**  O.K.
- **≠ 0**  Error.

Additional information

This function expects that the type field has not been eaten out of the buffer.
34.8.52 IP_SNMP_AGENT_ParseOctetString()

Description
Parses an OCTET STRING out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseOctetString(       IP_SNMP_AGENT_CONTEXT  *  pContext ,
 const  U8                    **  ppData ,
 U32                    *  pLen );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>ppData</td>
<td>Pointer where to store the pointer to the data in the message.</td>
</tr>
<tr>
<td>pLen</td>
<td>Pointer where to store the data len.</td>
</tr>
</tbody>
</table>

Return value

= 0    O.K.
≠ 0    Error.

Additional information

This function expects that the type field has not been eaten out of the buffer.
34.8.53  IP_SNMP_AGENT_ParseOID()

Description
Parses an OID out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseOID(       IP_SNMP_AGENT_CONTEXT  *  pContext ,
const  U8                    **  ppData ,
U32                    *  pLen );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>ppData</td>
<td>Pointer where to store the pointer to the data in the message.</td>
</tr>
<tr>
<td>pLen</td>
<td>Pointer where to store the data len.</td>
</tr>
</tbody>
</table>

Return value

- 0  O.K.
- ≠ 0  Error.

Additional information

This function expects that the type field has not been eaten out of the buffer.
34.8.54  IP_SNMP_AGENT_ParseOpaque()

Description
Parses an Opaque field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseOpaque(       IP_SNMP_AGENT_CONTEXT  *  pContext ,
                                   const  U8                    **  ppData ,
                                   U32                    *  pLen );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>ppData</td>
<td>Pointer where to store the pointer to the Opaque data in the message.</td>
</tr>
<tr>
<td>pLen</td>
<td>Pointer where to store the Opaque data len.</td>
</tr>
</tbody>
</table>

Return value
= 0    O.K.
≠ 0    Error.

Additional information
This function expects that the type field has not been eaten out of the buffer.
34.8.55    IP_SNMP_AGENT_ParseTimeTicks()

Description
Parses a 32-bit TimeTick field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseTimeTicks(IP_SNMP_AGENT_CONTEXT * pContext,
                                  U32 * pTimeTicks);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pTimeTicks</td>
<td>Pointer where to store the parsed TimeTicks.</td>
</tr>
</tbody>
</table>

Return value

- 0     O.K.
- ≠ 0   Error.

Additional information
This function expects that the type field has not been eaten out of the buffer.
34.8.56 IP_SNMP_AGENT_ParseUnsigned32()

Description
Parses an Unsigned32 field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseUnsigned32(IP_SNMP_AGENT_CONTEXT * pContext,
                                 U32                   * pUnsigned32);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pContext</code></td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td><code>pUnsigned32</code></td>
<td>Pointer where to store the parsed Unsigned32.</td>
</tr>
</tbody>
</table>

Return value

= 0 O.K.
≠ 0 Error.

Additional information

By design an Unsigned32 is a 32-bit unsigned value which does not mean that always 4 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.
34.8.57  IP_SNMP_AGENT_ParseUnsigned64()

Description
Parses an Unsigned64 field out of an SNMP message.

Prototype

```c
int IP_SNMP_AGENT_ParseUnsigned64(IP_SNMP_AGENT_CONTEXT * pContext,
                                  U64                   * pUnsigned64);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to an SNMP agent context.</td>
</tr>
<tr>
<td>pUnsigned64</td>
<td>Pointer where to store the parsed Unsigned64.</td>
</tr>
</tbody>
</table>

Return value

- 0      O.K.
- ≠ 0     Error.

Additional information

By design an Unsigned64 is a 64-bit unsigned value which does not mean that always 8 bytes are used in a message. This function expects that the type field has not been eaten out of the buffer.

Can only be used when `IP_SNMP_AGENT_SUPPORT_64_BIT_TYPES = 1.`
### 34.8.58 \textbf{IP\_SNMP\_AGENT\_DecodeOIDValue()}

**Description**

Parses and decodes an OID value of max \((2^{32}) - 1\) into an U32 to work with.

**Prototype**

```c
int IP_SNMP_AGENT_DecodeOIDValue(const U8 * pOID,
                                  U32 * pLen,
                                  U32 * pValue,
                                  const U8 ** ppNext);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOID</td>
<td>Pointer to next OID value to decode.</td>
</tr>
<tr>
<td>pLen</td>
<td>In Pointer to length of the OID at pOID. Out Pointer where to store the number of bytes decoded.</td>
</tr>
<tr>
<td>pValue</td>
<td>Pointer where to store the decoded OID value.</td>
</tr>
<tr>
<td>ppNext</td>
<td>Pointer to the pointer to the next OID value after the one processed. Can be NULL.</td>
</tr>
</tbody>
</table>

**Return value**

- \(= 0\) O.K.
- \(\neq 0\) Error.
34.8.59  IP_SNMP_AGENT_EncodeOIDValue()

Description

Encodes an OID value of max \(2^{32} - 1\) (U32) into a buffer.

Prototype

```c
int  IP_SNMP_AGENT_EncodeOIDValue ( U32    Value ,
         U8   *  pBuffer ,
         U32    BufferSize ,
         U8  **  ppNext ,
         U8   *  pNumEncodedBytes );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td>OID value to encode and store at pBuffer.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer where to store the encoded OID value.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of destination buffer.</td>
</tr>
<tr>
<td>ppNext</td>
<td>Pointer to the pointer to the next OID value after the one processed.</td>
</tr>
<tr>
<td>pNumEncodedBytes</td>
<td>Pointer where to store the number of encoded and stored bytes.</td>
</tr>
</tbody>
</table>

Return value

- \(= 0\)  O.K.
- \(\neq 0\)  Error.

Additional information

BufferSize needs to be big enough for the encoded OID value. If unsure use a buffer of 5 bytes as this is the maximum size of an encoded OID value or use at least enough bytes as required for the value in memory + 1 byte as a rough calculation. Examples:

127 will be encoded in one byte + 1 byte just to be on the safe side. 128 will be encoded in two bytes + 1 byte is required.
34.9 Data structures

34.9.1 Structure IP_SNMP_AGENT_API

Description

Used to provide an interface to external functions required for proper function of the SNMP agent.

Prototype

```c
typedef struct {
void (*pfInit)              ( void );
void (*pfDeInit)            ( void );
void (*pfLock)              ( void );
void (*pfUnlock)            ( void );
void* (*pfAllocSendBuffer)  ( void* pUserContext, U8** ppBuffer, U32 NumBytes, U8 IPAddrLen);
void (*pfFreeSendBuffer)    ( void* pUserContext, void* p, char SendCalled, int r);
int  (*pfSendTrapInform)    ( void* pContext, void* pUserContext, void* hBuffer, const U8* pData, U32 NumBytes, U8* pIPAddr, U16 Port, U8 IPAddrLen);
U32  (*pfGetTime)           ( void );
U32  (*pfSysTicks2SnmpTime)( U32 SysTicks );
U32  (*pfSnmpTime2SysTicks)( U32 SnmpTime );
} IP_SNMP_AGENT_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfInit</td>
<td>Callback for initialization required for any other callback such as pfLock/pfUnlock. Called from IP_SNMP_AGENT_Init().</td>
</tr>
<tr>
<td>pfDeInit</td>
<td>Callback for deinitialization called from IP_SNMP_AGENT_DeInit().</td>
</tr>
<tr>
<td>pfLock</td>
<td>Callback for API locking in a multitasking environment.</td>
</tr>
<tr>
<td>pfUnlock</td>
<td>Callback for API unlocking in a multitasking environment.</td>
</tr>
<tr>
<td>pfAllocSendBuffer</td>
<td>Callback for allocating a buffer to store a message that can be sent at a later time via pfSendTrapInform.</td>
</tr>
<tr>
<td>pfFreeSendBuffer</td>
<td>Callback for freeing a buffer previously allocated with pfAllocSendBuffer.</td>
</tr>
<tr>
<td>pfSendTrapInform</td>
<td>Callback for sending a previously allocated buffer that has been filled with a message to send.</td>
</tr>
<tr>
<td>pfGetTime</td>
<td>Callback to retrieve the current system time in milliseconds.</td>
</tr>
<tr>
<td>pfSysTicks2SnmpTime</td>
<td>Callback to convert the system time (typically 1ms) into SNMP time of 1/100 seconds since an epoch.</td>
</tr>
<tr>
<td>pfSnmpTime2SysTicks</td>
<td>Callback to convert an SNMP timestamp of 1/100 seconds since an epoch into the system time (typically 1ms).</td>
</tr>
</tbody>
</table>
34.9.2 Structure IP_SNMP_AGENT_PERM

Description

Used to grant permissions to a community that has been added to the SNMP agent.

Prototype

```c
typedef struct {
    const U8* pOID;
    U16 Len;
    U8  Perm;
} IP_SNMP_AGENT_PERM;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pOID</td>
<td>Pointer to OID value to grant access permissions.</td>
</tr>
<tr>
<td>Len</td>
<td>Length of OID located at pOID.</td>
</tr>
<tr>
<td>Perm</td>
<td>Permissions to grant at this OID value and its child OIDs.</td>
</tr>
</tbody>
</table>

Additional information

Permissions for various OID values can be set by using an array of IP_SNMP_AGENT_PERM entries that can then be used with IP_SNMP_AGENT_SetCommunityPerm(). Even if there is only one permission rule to set, there has to be an additional entry that always needs to be present. This last entry will specify the default permissions to grant for every OID that can not inherit permissions from a parent rule.

The default entry works the same way as any other entry but it needs to be the last entry and pOID/len are set to the values NULL/0.

The permissions that can be set for Perm are an ORRed value of the following masks:

<table>
<thead>
<tr>
<th>Define</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_SNMP_AGENT_PERM_READ_MASK</td>
<td>Grants read access to this community for the OID value specified in the entry and its child OIDs.</td>
</tr>
<tr>
<td>IP_SNMP_AGENT_PERM_WRITE_MASK</td>
<td>Grants write access to this community for the OID value specified in the entry and its child OIDs.</td>
</tr>
</tbody>
</table>
34.9.3 Structure IP_SNMP_AGENT_MIB2_SYSTEM_API

Description

System description represented at MIB-II at oid value 1.3.6.1.2.1.1. For more details please refer to [http://www.alvestrand.no/objectid/1.3.6.1.2.1.1.html](http://www.alvestrand.no/objectid/1.3.6.1.2.1.1.html).

A sample implementation can be found in the shipped SNMP agent samples.

Prototype

```c
typedef struct {
    const char* sSysDescr;
    const U8* pSysObjectID;
    U32 SysObjectIDLen;
    U32 (*pfGetSysUpTime) (void);
    int (*pfGetSetSysContact) (char* pBuffer, U32* pNumBytes, char IsWrite);
    int (*pfGetSetSysName) (char* pBuffer, U32* pNumBytes, char IsWrite);
    int (*pfGetSetSysLocation) (char* pBuffer, U32* pNumBytes, char IsWrite);
    U8 SysServices;
} IP_SNMP_AGENT_MIB2_SYSTEM_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sSysDescr</td>
<td>String including full name and version of the target and other information. Up to 255 characters + termination.</td>
</tr>
<tr>
<td>pSysObjectID</td>
<td>The vendor’s authoritative identification of the network management subsystem contained in the entity.</td>
</tr>
<tr>
<td>SysObjectIDLen</td>
<td>Length of the oid value at pSysObjectID.</td>
</tr>
<tr>
<td>pfGetSysUpTime</td>
<td>Time in in hundredths of a second since the network management portion of the system was last re-initialized.</td>
</tr>
<tr>
<td>pfGetSetSysContact</td>

<td>String including an administratively-assigned name for this managed node e.g. FQDN. Up to 255 characters + termination.</td>
</tr>
<tr>
<td>pfGetSetSysLocation</td>
<td>String including the physical location of this node. Up to 255 characters + termination.</td>
</tr>
<tr>
<td>SysServices</td>
<td>Value representing the services offered.</td>
</tr>
</tbody>
</table>
34.9.4 Structure IP_SNMP_AGENT_MIB2_INTERFACES_API

Description

Interfaces description represented at MIB-II at oid value 1.3.6.1.2.1.1. For more details please refer to http://www.alvestrand.no/objectid/1.3.6.1.2.1.1.html.

A sample implementation for embOS/IP is shipped with the SNMP agent in the file IP_SNMP_AGENT_MIB2_INTERFACES_embOSIP.c. The members of the structure are based on the SNMP structure of MIB-II interface counters.

To enable statistic counters in embOS/IP to provide the SNMP MIB-II interfaces counters with valid values please enable IP_SUPPORT_STATS_IFACE.
34.10 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the SNMP agent presented in the tables below have been measured on an ARM7 and a Cortex-M3 system. Details about the further configuration can be found in the sections of the specific example.

Configuration used

```c
#define IP_SNMP_AGENT_WORK_BUFFER 64
```

34.10.1 ROM usage on an ARM7 system

The following resource usage has been measured on an ARM7 system using IAR Embedded Workbench V6.30.6, Thumb mode, no interwork, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP SNMP agent</td>

Chapter 35

CoAP client/server (Add-on)

The embOS/IP Constrained Application Protocol (CoAP) client/server is an optional extension to embOS/IP. The CoAP client/server can be used with embOS/IP or with a different UDP/IP stack. All functions that are required to add a CoAP client/server to your application are described in this chapter.
35.1 embOS/IP CoAP

The embOS/IP CoAP client/server is an optional extension which adds CoAP support to the stack. It combines a maximum of performance with a small memory footprint. The CoAP server allows an embedded system to handle CoAP requests from a CoAP client. The CoAP client allows an embedded system to send request to a CoAP server.

The CoAP client/server implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[RFC 7252]</td>
<td>The Constrained Application Protocol (CoAP)</td>

<tr>
<td>.\IP\</td>
<td>Contains the CoAP sources and header files, IP_COAP*.</td>
</tr>
<tr>
<td>.\Windows\IP\CoAP_Server\</td>
<td>Contains the source, the project files and an executable to run the embOS/IP CoAP server on a Microsoft Windows host. Refer to <em>Using the CoAP samples</em> on page 994 for detailed information.</td>
</tr>
<tr>
<td>.\Windows\IP\CoAP_Client\</td>
<td>Contains the source, the project files and an executable to run the embOS/IP CoAP client on a Microsoft Windows host. Refer to <em>Using the CoAP samples</em> on page 994 for detailed information.</td>
</tr>
</tbody>
</table>
35.2 Feature list

- Low memory footprint.
- GET, DELETE, PUT, POST supported.
- Confirmable (CON) and non-confirmable (NON) requests supported.
- The server supports multiple clients.
- Independent of the UDP/IP stack: any stack with sockets can be used.
- Block transfer supported.
- Observe option supported.
- Example applications included.
- Demo with various option, request types, observable data included.
- Project for executable on PC for Microsoft Visual Studio included.
35.3 Requirements

**UDP/IP stack**

The embOS/IP CoAP client/server requires an UDP/IP stack. It is optimized for embOS/IP, but any RFC-compliant UDP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and an implementation which uses the socket API of embOS/IP.

**Multi tasking**

The client/server doesn’t required any multi-tasking environment to run. But the various CoAP APIs are not thread safe and should be protected accordingly if used in different threads.
35.4 CoAP background

The Constrained Application Protocol (CoAP) is an Internet of Things (IoT) protocol which allows machine to machine (M2M) communication with small footprint applications. It uses Uniform Resource Identifier (URI) to identify resources on the server. With its small and simple 4 bytes header, it’s ideal for devices with limited resources.

35.4.1 Protocol overview

The CoAP protocol implements a RESTful client-server based on four methods: GET, POST, PUT and DELETE. It could be embedded in the web transfer protocol thanks to CoAP proxys which could convert a web request (with address starting with coap://) into a CoAP request or used directly with a CoAP client.

The CoAP protocol is based on UDP (or DTLS for the secured version) and thus has to deal with potential message loss and repetition. It is a simple message exchange between endpoints. It relies on confirmable (CON) or non-confirmable (NON) messages.
**Message type**

They are four message types:

- **CON** messages used for requests. they expect to receive an acknowledgment (ACK) or a reset (RST), otherwise the message is retransmitted with an exponential back-off between retransmissions.
- **NON** messages don’t expect any confirmation. They could be used as request or response.
- **ACK** messages are acknowledgment of a CON.
- **RST** messages are sent as a reply when the server is not able to process the request.

**Requests**

A request is sent with a message of type CON or NON. There are four possible request methods defined by the CoAP protocol:

- **GET**: The GET method retrieves a representation for the information that currently corresponds to the resource identified by the request URI.
- **PUT**: The PUT method requests that the resource identified by the request URI be updated with the enclosed representation.
- **POST**: The POST method requests that the representation enclosed in the request be processed to create a new resource or update an existing one.
- **DELETE**: The DELETE method requests that the resource identified by the request URI be deleted.

For example a client would like to receive the value of the URI "/temp" on a server. It could send a "CON GET /temp". The server could directly answer with the data added to the ACK message (piggybacked ACK), or reply with an empty ACK and send a separate CON message with the data. This separate CON shall also be acknowledged.

![Diagram](image_url)

Depending on the requests parameters, different reply codes or error codes could be expected.
35.4.2 Message format

CoAP messages are encoded in a simple binary format. The message format starts with a fixed-size 4-byte header. This is followed by a variable-length Token value, which can be between 0 and 8 bytes long.

Following the Token value comes a sequence of zero or more CoAP Options in Type-Length-Value (TLV) format, optionally followed by a payload that takes up the rest of the datagram.

<table>
<thead>
<tr>
<th>Ver</th>
<th>T</th>
<th>TKL</th>
<th>Code</th>
<th>Message ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>++++++</td>
<td>++++++</td>
<td>++++++</td>
<td>++++++</td>
<td>++++++</td>
</tr>
</tbody>
</table>

The fields in the header are defined as follow:

**Version (Ver):**
2-bit unsigned integer. Indicates the CoAP version number. This implementation sets this field to 1 (01 binary).

**Type (T):**
2-bit unsigned integer. Indicates if this message is of type Confirmable (0), Non-confirmable (1), Acknowledgement (2), or Reset (3).

**Token Length (TKL):**
4-bit unsigned integer. Indicates the length of the variable-length Token field (0-8 bytes).

**Code:**
8-bit unsigned integer, split into a 3-bit class (most significant bits) and a 5-bit detail (least significant bits), documented as “c.dd” where “c” is a digit from 0 to 7 for the 3-bit subfield and “dd” are two digits from 00 to 31 for the 5-bit subfield. The class can indicate a request (0), a success response (2), a client error response (4), or a server error response (5). As a special case, Code 0.00 indicates an Empty message. In case of a request, the Code field indicates the Request Method; in case of a response, a Response Code.

**Message ID:**
16-bit unsigned integer in network byte order. Used to detect message duplication and to match messages of type Acknowledgment/Reset to messages of type Confirmable/Non-confirmable.

The header is followed by the Token value, which may be 0 to 8 bytes, as specified by the Token Length field. Header and Token are followed by zero or more Options. An Option can be followed by the end of the message, by another Option, or by the Payload Marker (0xFF) and the payload.
35.4.3  Response code

After receiving and interpreting a request, a server responds with a CoAP response. A response is identified by the Code field in the CoAP header being set to a Response Code. Similar to the HTTP Status Code, the CoAP Response Code indicates the result of the attempt to understand and satisfy the request.

```
  0 1 2 3 4 5 6 7
  ++++++++------
  |class|  detail |
  ++++++++------
```

The upper three bits of the 8-bit Response Code number define the class of response. The lower five bits do not have any categorization role; they give additional detail to the overall class.

As a human-readable notation for specifications and protocol diagnostics, CoAP code numbers including the Response Code are documented in the format “c.dd”, where “c” is the class in decimal, and “dd” is the detail as a two-digit decimal. For example, “Forbidden” is written as 4.03 -- indicating an 8-bit code value of hexadecimal 0x83 (4*32+3) or decimal 131 (4*32+3).

There are 3 classes of Response Codes:

- 2 - Success: The request was successfully received, understood, and accepted.
- 4 - Client Error: The request contains bad syntax or cannot be fulfilled.
- 5 - Server Error: The server failed to fulfill an apparently valid request.

Here are the basic response code from RFC 7252:

```

</tbody>
</table>
+-----+------------------+
```
35.4.4 CoAP options

Both requests and responses may include a list of one or more options. CoAP defines a single set of options that are used in both requests and responses:

Options are present to parametrize the request or the response. Some of the options are:

**Content-Format:**
Used to specify the format of a data (plain/text, binary, ...).

**ETag:**
An entity-tag is intended for use as a resource-local identifier for differentiating between representations of the same resource that vary over time. When sending a response to a request (typically a GET), the server may provide an ETag identifying the current state/value of the entity. When a client sends a GET request with an ETag, the server can issue a 2.03 Valid response in place of a 2.05 Content response if the ETag match the current representation.

**Max-Age:**
The Max-Age option indicates the maximum time (in s) a response may be cached before it is considered not fresh.

**Uri-Path:**
This is one of the option used to define the URI (with Uri-Host, Uri-Port and Uri-Query). Uri-Path specifies one segment of the absolute path to the resource (without the leading '/').

**Accept:**
The CoAP Accept option can be used to indicate which Content-Format is acceptable to the client.

**If-Match:**
The If-Match option may be used to make a request conditional on the current existence or value of an ETag for one or more representations of the target resource. The value of an If-Match option is either an ETag or the empty string. An If-Match option with an ETag matches a representation with that exact ETag. The If-Match with an empty string matches all representations as long as the data exists already. It is typically used in a PUT request to protect the update of a data.

**If-None-Match:**
The If-None-Match option may be used to make a request conditional on the nonexistence of the target resource. If-None-Match is useful for resource creation requests, such as POST requests.

There are more options defined, refer to the RFC for the complete list.

Note that some options are repeatable. This means they could appear more than once per CoAP message.

35.4.5 Retry mechanism

Confirmable messages should be acknowledged. If the CON or the ACK doesn't reach its target, the CON is retransmitted with an exponential back-off between the retransmissions.
Per default, there are four retransmissions. The initial timeout between the initial message and the first retransmission is a random number between two and three seconds (with the default RFC values).

### 35.4.6 Block transfer

Basic CoAP messages work well for small payloads, however, it might be requested to transfer larger amount of data. CoAP is based on datagram transport layer and is thus subject to fragmentation.

Instead of relying on IP fragmentation, CoAP uses “Block” options in order to transfer multiple blocks of information from a resource representation in multiple request-response pairs.

Two block options are defined:
- Block1 is present in a request. Typically in a PUT or POST to send data to the server.
- Block2 is present in a response. Typically in a GET response to send the data in chunks.

The block option is composed of three values:

**Block Size:**

The possible block sizes are power of 2 values between 16 and 1024 included.

**More Flag:**

The more flag bit is set to 1 to indicate more blocks are to be expected. If set to 0 this means the current block is the last block of the transfer.

**NUM:**

This is the block number. Block number 0 indicates the first block.

The notation used to describe block is `<block type>:<NUM>/<More>/<Block Size>`. For example the first Block2 of a transfer where the More flag is set and the size of block is 128 bytes is written `2:0/1/128`.

The block size used in the transfer is always the smaller of the sizes proposed by the client and the server. For example if a client makes a request with a block size of 128, but the server can only handle blocks of 64 bytes, then the server will reply with a block of 64 bytes and the following request from the client will also use blocks of 64 bytes.

There are two other options Size1 and Size2. Size1 (resp. Size2) is optionally used to give an indication of the total size of a Block1 (resp. Block2) transfer.

The following example gives a simple overview of a GET request with a Block2 option of 128 bytes.
35.4.7 Observe

The Observe option specifies a way for a client to register to a server resource. This allows a client to follow the evolution of a resource over a period of time.

The client (observer) registers to a server specific resource and receives a notification each time this resource is updated.

**Request**

In order to register, the client sends a GET with the Observe option set to 0. To de-register its interest, the client could either send another GET on the resource with Observe set to 1, or just “forget” the registered observe request. In this last case, when the server will send a notification on the resource, the client will reply with a RST message and the server will understand that the registration is not valid anymore.

In order to identify the following notifications, the client must provide a token in the request.
Notification

Notifications are additional responses sent by the server in reply to the single extended GET request that created the registration. Each notification includes the token specified by the client in the request.

Notifications typically have a 2.05 (Content) response code. They include an Observe Option with a sequence number for reordering detection.

The notifications could have a different type than the one used for the request. For example if a registration is made with a CON, the server will reply with an ACK, but the following notifications could either be CON or NON or a mix of both. For example a server could decide to send a NON at a “MaxAge” period and to send a CON when the value is actually changing.

Of course, the observe notifications could use blocks when data to transfer is big. CON messages are also retransmitted if needed. If the retransmission maximum count is reached, the observation is canceled.

35.4.8 Built-In resource discovery

The discovery of resources offered by a CoAP endpoint is extremely important in machine-to-machine applications where there are no humans in the loop and static interfaces result in fragility.

Using the default UDP port, a client sends a GET request to the server with the Uri-Path set to “.well-known/core”. The server will provide a response following the CoRE Link Format describing the resources present on the server.

An example of this discover reply is seen below. Note that line breaks were added for readability purpose and are not part of the actual message:

```
</obs>;obs;title="Simple observable data.",
</test>;title="test entry",
</separate>;title="simple variable with GET with LATE reply",
</BlockTransfer/ObsData>;obs;title="Observable data block.",
</ObsSensor>;obs;title="Observable value.",
</BlockTransfer/Data128bytes>;title="Textual value. GET and PUT, block support. Size 128 Bytes.",
</BlockTransfer/DelayedBlock>;title="Textual value. GET late reply with block support.",
</DataSupportingDelete>;title="Binary value (int). GET piggybacked, Support DELETE",
</temperature/average>;title="Textual value. GET late reply.",
```
35.4.9 Implementation choices

A few choices were made for this CoAP implementation.

A POST on an existing resource is treated as a PUT. But a PUT with a URI that doesn't correspond to any resource is treated as an error (and not as a POST).

In order to reduce RAM usage, the implementation is stateless. This means in a block transfer it doesn't check the block sequence. It is indicating for example by clearing the "More" bit in a Block1 option when sending a "2.31 Continue" acknowledgment. It is of course possible for the application to perform this test as the block information is given in all payload related callbacks.

When the server receives a GET request on a branch (for example on "/temperature"), it will automatically reply with the list of all resources under this branch (like "/temperature/meas", "/temperature/average", ...) unless a resource exists with the actual Uri-Path ("/temperature").

The server couldn't be used as a proxy. Therefore it doesn't support the Proxy-Uri and Proxy-Scheme options and replies with an error "5.05 Proxying Not Supported" in this case.
35.5 Using the CoAP samples

Ready to use examples for Microsoft Windows and embOS/IP are supplied. If you use another UDP/IP stack, the samples have to be adapted.

35.5.1 Running the sample on target hardware

The embOS/IP CoAP sample applications should always be the first step to check the proper function of the CoAP client/server with your target hardware.

Add all source files located in the following directories (and their subdirectories) to your project and update the include path:

- Application\n- Config\n- Inc\n- IP\

It is recommended that you keep the provided folder structure.

The sample application can be used on the most targets without the need for changing any of the configuration flags.

35.5.2 Using the Windows samples

If you have MS Visual C++ 6.00 or any later version available, you will be able to work with a Windows sample projects using the embOS/IP CoAP client/server. If you do not have the Microsoft compiler, a precompiled executable is also supplied.

Building the sample program

Open the workspace .dsw with MS Visual Studio (for example, double-clicking it). There is no further configuration necessary. You should be able to build the application without any error or warning message.

The server uses the IP address of the host PC on which it runs.

35.5.3 Sample CoAP server application

The sample server application initializes and configures a CoAP server (IP_COAP_SERVER_CONTEXT) with a few resources (IP_COAP_SERVER_DATA). Each resource provides one or more handlers to process the requests (GET, PUT, ...). These handlers are simple example and not representative of a full application.

The applications defines the number or possible simultaneous “connections” of the server. It’s not actual connections like with TCP, but more a context to handle a transfer. As a connection is closed once the transfer is completed, a server could handle way more clients than configured connections, especially when using confirmable messages since they are retransmitted when not acknowledged which could mitigate potential congestions.

After the server configurations, the server enters an infinite loop to call periodically the IP_COAP_SERVER_Process() function. This function does all the CoAP server processing:

- Handling of requests from clients.
- Retry mechanism of CON messages.
- Notification of observed resources.

35.5.4 Server callbacks description

The resource are defined by the IP_COAP_SERVER_DATA and have several function pointers to allow and handle the various procedure.

All the callbacks have as parameter an IP_COAP_CALLBACK_PARAM which gives information on the message like header, options or block parameters.
Refer to Callback *pfGETPayload* on page 1076, Callback *pfPUTPayload* on page 1079 and Callback *pfDELHandler* on page 1081.

### 35.5.5 Testing the server

A possibility to test the server is to use the CoAP plug-in for firefox called Copper:

![CoAP ping and discover](image)

Start by sending a CoAP ping (*CON Empty*) to verify the server is receiving data. Then performs a discover (*GET .well-known/core*) to populate the resource tree.

### 35.5.6 Sample CoAP client application

The server address used for testing is defined in `COAP_SERVER`. By default it uses the test server `coap://vs0.inf.ethz.ch`. As the resource requested in the sample client application are also defined in the sample server application, the client could use the IP address of the running sample server application.

For example if both Windows samples are used, the `COAP_SERVER` define should be set to the localhost `127.0.0.1`.

The sample client application initializes first a CoAP client (`IP_COAP_CLIENT_CONTEXT`). A client is composed of a request array (`IP_COAP_CLIENT_REQUEST`). As a client may receive asynchronous messages (like observe notifications, retransmit of messages), it performs an infinite loop similarly to the server.

The main processing of the client could be summarized by:

```c
while(1) {
    IP_COAP_CLIENT_Process(&_COAPClient);
    //
    // Check if there is a pending result.
    //
    r = IP_COAP_CLIENT_GetLastResult(&_COAPClient, &ResultCode, &pError, &ErrorLength);
    if (r >= 0) {
        _HandleResult(r, ResultCode, pError, ErrorLength);
    }
}```
This way the client could handle requests and observations in parallel.

If the client is using only one request (i.e. connection) at a time (for example NSTART is defined as 1 as per default), and if the client doesn’t make use of the observe functionality, the main loop could be avoided and instead have just a simpler request handler.

The processing would be similar to:

```c
// Check if there is a free request to execute a new one.
if (IP_COAP_CLIENT_GetFreeRequestIdx(&_COAPClient, &Index) == IP_COAP_RETURN_OK) {
    // Initialize the new request.
    r = IP_COAP_CLIENT_SetCommand(&_COAPClient, Index, ...);
    r = IP_COAP_CLIENT_SetOptionXXX(&_COAPClient, Index, ...);
    // Send the request.
    r = IP_COAP_CLIENT_BuildAndSend(&_COAPClient, Index);
    // Do CoAP processing until the reply is received.
    do {
        IP_COAP_CLIENT_Process(&_COAPClient);
        // Get last result.
        r = IP_COAP_CLIENT_GetLastResult(&_COAPClient, &ResultCode, &pError, &ErrorLength);
    } while (r < 0);
    _HandleResult(r, ResultCode, pError, ErrorLength);
}
```

### 35.5.7 Client callbacks description

When sending a GET, POST or PUT request, the user is invited to define a callback to handle the payload through the function `IP_COAP_CLIENT_SetPayloadHandler()`.

A payload callback have as parameter an `IP_COAP_CALLBACK_PARAM` which gives information on the message like header, options or block parameters.

Refer to `Callback PF_CLIENT_PAYLOAD` on page 1085.
35.6 CoAP configuration

The embOS/IP CoAP client/server can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

35.6.1 CoAP configuration macro types

The following types of configuration macros exist:

**Binary switches "B"

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

**Function replacements "F"

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

35.6.2 Configuration switches

<table>
<thead>
<tr>

</table>

### 35.7.1 Server
35.7.1.1   IP_COAP_SERVER_Init()

Description
Initializes the CoAP server context. This function needs to be called first.

Prototype

```c
int IP_COAP_SERVER_Init(       IP_COAP_SERVER_CONTEXT *  pContext ,
U8                     *  pMsgBuffer ,
U16                      MsgBufferSize ,
const  IP_COAP_API            *  pAPI );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context to initialize.</td>
</tr>
<tr>
<td>pMsgBuffer</td>
<td>Buffer used to handle UDP packets.</td>
</tr>
<tr>
<td>MsgBufferSize</td>
<td>Size of pMsgBuffer in bytes.</td>
</tr>
<tr>
<td>pAPI</td>
<td>API used for UDP transfer and time.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`   Success.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information

If possible, the message buffer should be as big as the MTU but since fragmentation is not used, this is useless to have a message buffer bigger than 1500 bytes.

The default block size will be adjusted to take into account the buffer size. Thus if the buffer is small (i.e. 512 bytes) the default block size will be adjusted (to 256 in this case).

APIs are used to send and receive UDP packets. The third one is used to retrieve the time in ms.

Example

```c
static IP_COAP_SERVER_CONTEXT      _COAPServer ;
static IP_COAP_CONN_INFO           _ConnInfo ;
static U8                          _MsgBuffer [ 1500 ];
static IP_COAP_SERVER_CLIENT_INFO  _COAPClientInfo [ IP_COAP_MAX_NUM_CLIENT ];
static IP_COAP_OBSERVER            _COAPObservers [ IP_COAP_MAX_NUM_OBS ];

static const IP_COAP_API _APP_Api = {
    _APP_Receive ,
    _APP_Send ,
    _APP_GetTimeMs
};

void  Server ( void )  {
    // Initializes the CoAP server.
    //
    IP_COAP_SERVER_Init( & _COAPServer ,  _MsgBuffer ,  sizeof( _MsgBuffer ),  & _APP_Api );
    //
    // Add the clients and observers buffers.
    //
    IP_COAP_SERVER_AddClientBuffer( & _COAPServer ,  & _COAPClientInfo[0][ ],  IP_COAP_MAX_NUM_CLIENT );
    IP_COAP_SERVER_AddObserverBuffer( & _COAPServer ,  & _COAPObservers[0][ ] ,  IP_COAP_MAX_NUM_OBS );
    //
    // Add a handler to perform POST command.
    //
    IP_COAP_SERVER_SetPOSTHandler( & _COAPServer ,  _POSTCreateEntry );
    //
    // Configure a default block size.
    //
```
IP_COAP_SERVER_SetDefaultBlockSize(& COAPServer, 32);
//
// Configuration of the server by adding ServerData structures.
//
_ConfigureServer();
//
_ConnInfo.Family = IP_COAP_IPV4;
_ConnInfo.Port = IP_COAP_DEFAULT_PORT;
//
// Run the main loop.
//
while (1) {
//
// Call regularly the CoAP processing function.
//
IP_COAP_SERVER_Process(& COAPServer, & _ConnInfo);
//
// Perform the application processing.
//
_ApplicationProcessing();
}
### 35.7.1.2 IP_COAP_SERVER_Process()

**Description**

Called periodically to handle CoAP server processing: handles pending actions, read and handle received packet.

**Prototype**

```c
int IP_COAP_SERVER_Process(IP_COAP_SERVER_CONTEXT * pContext,
                           IP_COAP_CONN_INFO      * pConnInfo);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the server CoAP context.</td>
</tr>
<tr>
<td>pConnInfo</td>
<td>Pointer on the connection info used to receive UDP packets.</td>
</tr>
</tbody>
</table>

**Return value**

- `== IP_COAP_RETURN_OK` Success.
- `!= IP_COAP_RETURN_OK` Error.

**Additional information**

IP_COAP_SERVER_Process() is not thread safe. If it is used in a multithreading environment, it shall be proofed by the user that no calls to configuration functions (such as _AddData(), _RemoveData(), ...) are made while this function runs.

Refer to IP_COAP_SERVER_Init on page 1002 for usage example.
35.7.1.3  IP_COAP_SERVER_GetMsgBuffer()

Description
Returns the buffer used to send messages.

Prototype

U8 *IP_COAP_SERVER_GetMsgBuffer ( IP_COAP_SERVER_CONTEXT * pContext,
                                           U16 * pMsgLength);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pMsgLength</td>
<td>Filled with buffer length.</td>
</tr>
</tbody>
</table>

Return value

≠ NULL  Pointer on the message buffer.
35.7.1.4 IP_COAP_SERVER_AddData()

Description
Adds a data entry to the server.

Prototype

```c
int IP_COAP_SERVER_AddData(IP_COAP_SERVER_CONTEXT * pContext,
                             IP_COAP_SERVER_DATA   * pData);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pData</td>
<td>Data to add.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  Success.
- ≠ `IP_COAP_RETURN_OK`  Error.

Refer to Structure `IP_COAP_SERVER_DATA` on page 1071 for usage example.
35.7.1.5  IP_COAP_SERVER_RemoveData()

**Description**
Removes a previously configured data from the server.

**Prototype**

```c
int IP_COAP_SERVER_RemoveData(IP_COAP_SERVER_CONTEXT * pContext,
                               IP_COAP_SERVER_DATA    * pData);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pData</td>
<td>Data to remove.</td>
</tr>
</tbody>
</table>

**Return value**

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error, data not found.
35.7.1.6 IP_COAP_SERVER_AddClientBuffer()

**Description**
Adds a pool of client structures to be used by the server to handle request. The number of clients represents the number of clients that could be handled at the same time (request on-going).

**Prototype**

```c
int IP_COAP_SERVER_AddClientBuffer(IP_COAP_SERVER_CONTEXT * pContext,
                                   IP_COAP_SERVER_CLIENT_INFO * pClientInfo,
                                   unsigned NumClientInfo);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pClientInfo</td>
<td>Start of the client pool.</td>
</tr>
<tr>
<td>NumClientInfo</td>
<td>Number of clients in the given pool.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK` Success.
- ≠ `IP_COAP_RETURN_OK` Error.

**Additional information**
At least one client is mandatory. Without any client configured the server won’t be able to handle requests.

This represents the total number of clients/connections active at the same time. Since a connection is closed when the transfer is completed, a server could handle much more clients than this configuration, depending on the traffic generated by each client.

Refer to `IP_COAP_SERVER_Init` on page 1002 for usage example.
### 35.7.1.7 IP_COAP_SERVER_AddObserverBuffer()

#### Description

Adds a pool of observer structures to be used by the server to handle observer request. When the pool is full, no more observer request could be handled.

#### Prototype

```c
int IP_COAP_SERVER_AddObserverBuffer(IP_COAP_SERVER_CONTEXT * pContext,
                                      IP_COAP_OBSERVER       * pObs,
                                      unsigned                  NumObservers);
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pObs</td>
<td>Start of the observer pool.</td>
</tr>
<tr>
<td>NumObservers</td>
<td>Number of observers in the given pool.</td>
</tr>
</tbody>
</table>

#### Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Refer to *IP_COAP_SERVER_Init* on page 1002 for usage example.
35.7.1.8 IP_COAP_SERVER_UpdateData()

Description
Called by the user to indicate data are ready or changed. It is used in two cases:
- GET with a separate reply (ACK then reply in another request) to indicate the reply is ready to be sent.
- Observable data has changed. This needs to be called each time an observable data changes.

Prototype

```c
int IP_COAP_SERVER_UpdateData(IP_COAP_SERVER_CONTEXT * pContext,
                                IP_COAP_SERVER_DATA * pData,
                                U8 ObsUpdateType,
                                unsigned AutoETag);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pData</td>
<td>Data that is ready or changed</td>
</tr>
<tr>
<td>ObsUpdateType</td>
<td>Type of the request to send in case of observable data update:</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_TYPE_CON.</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_TYPE_NON.</td>
</tr>
<tr>
<td>AutoETag</td>
<td>Flag to generate a new ETag automatically.</td>
</tr>
<tr>
<td></td>
<td>• 1: Automatic ETag increment.</td>
</tr>
<tr>
<td></td>
<td>• 0: No change on ETag.</td>
</tr>
</tbody>
</table>

Return value

- = IP_COAP_RETURN_OK Success.
- ≠ IP_COAP_RETURN_OK Error.

Additional information

When set to 1, AutoETag flag will increase by 1 the ETag value.
35.7.1.9 IP_COAP_SERVER_SetDefaultBlockSize()

Description
Configures the default block size used by the server.

Prototype

```c
int IP_COAP_SERVER_SetDefaultBlockSize(IP_COAP_SERVER_CONTEXT * pContext,
                                       U16                      BlockSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>BlockSize</td>
<td>Requested block size in bytes.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Refer to `IP_COAP_SERVER_Init` on page 1002 for usage example.
35.7.1.10 IP_COAP_SERVER_SetPOSTHandler()

Description
Configures the callback used when receiving a POST request to create a new server data entry.

Prototype

```c
int IP_COAP_SERVER_SetPOSTHandler(IP_COAP_SERVER_CONTEXT * pContext,
                                   PF_POST_HANDLER            pfPOSTCreateEntry);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>pfPOSTCreateEntry</td>
<td>Pointer on the function to call.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- `IP_COAP_RETURN_ERROR` Error.

Refer to `IP_COAP_SERVER_Init` on page 1002 for usage example.
35.7.1.11  IP_COAP_SERVER_ConfigSet()

Description
Activates the given options from the server configuration.

Prototype

```
int IP_COAP_SERVER_ConfigSet (IP_COAP_SERVER_CONTEXT * pContext,
                               U8 ConfigMask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>ConfigMask</td>
<td>Mask of the configurable options (IP_COAP_CONFIG_xxx).</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- `IP_COAP_RETURN_OK` Error.

Additional information

The possible options to configure are:

- `IP_COAP_CONFIG_DISABLE_BLOCK1` to disable Block1 usage.
- `IP_COAP_CONFIG_DISABLE_BLOCK2` to disable Block2 usage.
- `IP_COAP_CONFIG_DISABLE_BLOCKS` to disable both Block1 and Block2.
- `IP_COAP_CONFIG_DISABLE_OBSERVE` to disable Observe option support.
35.7.1.12 IP_COAP_SERVER_ConfigUnset
35.7.1.13 IP_COAP_SERVER_SetURIPort()

**Description**
Configures the UDP port to be sent as URI-Port in reply to a GET.

**Prototype**

```c
int IP_COAP_SERVER_SetURIPort(IP_COAP_SERVER_CONTEXT * pContext,
                               U16                      Port);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>Port</td>
<td>UDP port.</td>
</tr>
</tbody>
</table>

**Return value**

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

**Additional information**
The server data should be configured to send the URI-Port option in a GET reply. It has no impact on the actual port used in the IP_COAP_CONN_INFO structure.
35.7.1.14 IP_COAP_SERVER_SetHostName()

Description
Configures the host name to be sent as URI-Host in reply to a GET.

Prototype

```c
int IP_COAP_SERVER_SetHostName(       IP_COAP_SERVER_CONTEXT *  pContext,
                                   const char                    *  sHostName );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>sHostName</td>
<td>Null terminating string with the hostname.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK Success.
- IP_COAP_RETURN_OK Error.

Additional information
The server data should be configured to send the URI-Host option in a GET reply.
35.7.1.15  IP_COAP_SERVER_SetErrorDescription()

Description

Configures a temporary error description to be sent as payload in an error message. This is typically called from payload callbacks.

Prototype

\[
\text{int IP_COAP_SERVER_SetErrorDescription( IP_COAP_SERVER_CONTEXT * pContext, const char * sErrorDesc);}
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Server context.</td>
</tr>
<tr>
<td>sErrorDesc</td>
<td>Null terminating string with the error description.</td>
</tr>
</tbody>
</table>

Return value

\[
\begin{align*}
\text{=} & \text{ IP_COAP_RETURN_OK} & \text{Success.} \\
\ne & \text{IP_COAP_RETURN_OK} & \text{Error.}
\end{align*}
\]
35.7.2 Client
35.7.2.1 IP_COAP_CLIENT_Init()

Description

Initializes a CoAP client.

Prototype

```c
int IP_COAP_CLIENT_Init(       IP_COAP_CLIENT_CONTEXT * pContext,
                               U8                     * pMsgBuffer ,
                               U16                      MsgBufferSize ,
                               const IP_COAP_API            *  pAPI );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>pMsgBuffer</td>
<td>Buffer used to handle UDP packets.</td>
</tr>
<tr>
<td>MsgBufferSize</td>
<td>Size of pMsgBuffer in bytes.</td>
</tr>
<tr>
<td>pAPI</td>
<td>API used for UDP transfer and time.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK`   Success.
- `≠ IP_COAP_RETURN_OK`  Error.

Additional information

If possible, the message buffer should be as big as the MTU but since fragmentation is not used, this is useless to have a message buffer bigger than 1500 bytes.

The default block size will be adjusted to take into account the buffer size. Thus if the buffer is small (i.e. 512 bytes) the default block size will be adjusted (to 256 in this case).

APIs are used to send and receive UDP packets. The third one is used to retrieve the time in ms.

Example

```c
static IP_COAP_CLIENT_CONTEXT _COAPClient ;
static IP_COAP_CONN_INFO     _ConnInfo ;
static U8                     _MsgBuffer[1500];

static const IP_COAP_API      _APP_Api = {         
    _APP_Receive ,
    _APP_Send ,
    _APP_GetTimeMs
};

void _ClientInit ( void ) {
    // // Initializes the CoAP client .
    // IP_COAP_CLIENT_Init( & _COAPClient , & _MsgBuffer[0], sizeof( _MsgBuffer ), & _APP_Api );
    // // Configure server address .
    // _ConnInfo . Family   = IP_COAP_IPV4 ;
    _ConnInfo . Port     = COAP_PORT ;
    _ConnInfo . IPAddrV4 = COAP_SERVER_ADDRESS ;
    IP_COAP_CLIENT_SetServerAddress( & _COAPClient , & _ConnInfo );
}
```
35.7.2.2   IP_COAP_CLIENT_Process()

Description
Periodic function called to manage CoAP request and observer of a client.

Prototype

```c
int IP_COAP_CLIENT_Process(IP_COAP_CLIENT_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  A free request is present.
- `≠ IP_COAP_RETURN_OK` No free request available.

Refer to *Sample CoAP client application* on page 995 for usage example.
35.7.2.3  IP_COAP_CLIENT_GetFreeRequestIdx()

Description
Returns a free request. Should be called to get the index of a free request to be used to configure and send the request.

Prototype

```c
int IP_COAP_CLIENT_GetFreeRequestIdx(IP_COAP_CLIENT_CONTEXT * pContext,
                                     unsigned                * pIndex);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>pIndex</td>
<td>Filled with the free request index.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` A free request is present.
- `# IP_COAP_RETURN_OK` No free request available.

Refer to Sample CoAP client application on page 995 for usage example.
35.7.2.4 IP_COAP_CLIENT_AbortRequestIdx()

Description
Aborts an on-going request.

Prototype

```c
int IP_COAP_CLIENT_AbortRequestIdx(IP_COAP_CLIENT_CONTEXT * pContext,
                                   unsigned Index);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the request to abort.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- ≠ `IP_COAP_RETURN_OK` Error.
35.7.2.5 IP_COAP_CLIENT_SetServerAddress()

Description
Configures the UDP parameters of the server.

Prototype

```c
int IP_COAP_CLIENT_SetServerAddress(IP_COAP_CLIENT_CONTEXT * pContext,
                                IP_COAP_CONN_INFO      * pConnInfo);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>pConnInfo</td>
<td>UDP connection information.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Refer to `IP_COAP_CLIENT_Init` on page 1019 for usage example.
35.7.2.6  IP_COAP_CLIENT_SetDefaultBlockSize()

Description
Sets the default block size to be used by the client.

Prototype

```c
int  IP_COAPCLIENT_SetDefaultBlockSize(IP_COAP_CLIENT_CONTEXT * pContext,
U16                      BlockSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>BlockSize</td>
<td>Size of the block in bytes.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  Success.
- ≠ `IP_COAP_RETURN_OK` Error.

Additional information

The given block size will be adjusted if it is too big for the configured message buffer size. A specific request could still be configured with another block size by calling `IP_COAP_CLIENT_SetOptionBlock()`.
35.7.2.7  IP_COAP_CLIENT_SetCommand()

Description
Configures the request type and code.

Prototype

```c
int IP_COAP_CLIENT_SetCommand(IP_COAP_CLIENT_CONTEXT * pContext,
                              unsigned                  Index,
                              U8                       Type,
                              U8                       Code);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Free request index.</td>
</tr>
<tr>
<td>Type</td>
<td>Type of the request:</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_TYPE_CON.</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_TYPE_NON.</td>
</tr>
<tr>
<td>Code</td>
<td>Code of the request:</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_GET.</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_DEL.</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_PUT.</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_POST.</td>
</tr>
</tbody>
</table>

Return value

- = IP_COAP_RETURN_OK  Success.
≠ IP_COAP_RETURN_OK    Error.

Example

```c
// Build the request with the given free index.
IP_COAP_CLIENT_SetCommand(&_COAPClient, Index, IP_COAP_TYPE_CON, IP_COAP_CODE_REQ_GET);
IP_COAP_CLIENT_SetOptionURIPath(&_COAPClient, Index, (U8*)".well-known/core", 16);
IP_COAP_CLIENT_SetOptionBlock(&_COAPClient, Index, 128);
IP_COAP_CLIENT_SetPayloadHandler(&_COAPClient, Index, _DISCOVER_Handler);
//
r = IP_COAP_CLIENT_BuildAndSend(&_COAPClient, Index);
```
35.7.2.8  IP_COAP_CLIENT_SetToken()

**Description**
Configures the token of a request.

**Prototype**

```c
int IP_COAP_CLIENT_SetToken(IP_COAP_CLIENT_CONTEXT * pContext,
                          unsigned Index,
                          U8 * pToken,
                          U8 TokenLength);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Free request index.</td>
</tr>
<tr>
<td>pToken</td>
<td>Pointer on the token.</td>
</tr>
<tr>
<td>TokenLength</td>
<td>Length of the token.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.
35.7.2.9 IP_COAP_CLIENT_SetPayloadHandler()

Description
Configures the callback used to manage the payload of the request. For GET it’s the function that will be called with the data when receiving the reply. For PUT/POST, this is the function that will be used to add the data in the request message.

Prototype

```c
int IP_COAP_CLIENT_SetPayloadHandler(IP_COAP_CLIENT_CONTEXT * pContext,
                                      unsigned                  Index,
                                      PF_CLIENT_PAYLOAD          pf);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Free request index.</td>
</tr>
<tr>
<td>pf</td>
<td>Pointer on the callback.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Refer to `IP_COAP_CLIENT_SetCommand` on page 1025 for usage example.
35.7.2.10  IP_COAP_CLIENT_SetReplyWaitTime()

Description
Configures the time to wait for the reply after sending the request. This is intended when using multicast/broadcast request.

Prototype

```c
int  IP_COAP_CLIENT_SetReplyWaitTime ( IP_COAP_CLIENT_CONTEXT *  pContext,
                        unsigned                  Index,
                        U32                      Seconds);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Free request index.</td>
</tr>
<tr>
<td>Seconds</td>
<td>Number of seconds to wait for the reply.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK  Success.
- ≠ IP_COAP_RETURN_OK Error.

Additional information

When sending a request to a multicast/broadcast address, the type should be set to NON. The server should wait a random time before sending the reply (up to DEFAULT_LEISURE). The random time could be bigger than the normal wait time. This function is there to alter the wait time in this specific case.
35.7.2.11 IP_COAP_CLIENT_BuildAndSend()

Description
Builds the CoAP message and sends it based on a configured request.

Prototype

```c
int IP_COAP_CLIENT_BuildAndSend(IP_COAP_CLIENT_CONTEXT * pContext,
                                 unsigned Index);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Configured request index to build and send.</td>
</tr>
</tbody>
</table>

Return value

≥ 0       Success.
< 0       Error.

Refer to IP_COAP_CLIENT_SetCommand on page 1025 for usage example.
35.7.2.12 IP_COAP_CLIENT_GetLastResult()

**Description**

Returns the status and information when a request is completed.

**Prototype**

```c
int IP_COAP_CLIENT_GetLastResult (IP_COAP_CLIENT_CONTEXT * pContext,
             U8                      * pCode,
             U8                     ** ppError,
             U16                     * pLength);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>pCode</td>
<td>To be filled with the CoAP code of the result.</td>
</tr>
<tr>
<td>ppError</td>
<td>In case of error sent by the server (class 2 or 4), it may contain a string with a comment on the error. To be ignored in case of success or other error classes.</td>
</tr>
<tr>
<td>pLength</td>
<td>Length of the <code>ppError</code>.</td>
</tr>
</tbody>
</table>

**Return value**

- \( \geq 0 \)  Index of the completed request.
- \(< 0 \)  No request just finished.

**Additional information**

When a request is sent, it is needed to call periodically `IP_COAP_CLIENT_process()` and `IP_COAP_CLIENT_GetLastResult()` to process the request and check when it is completed.

The data pointed by `ppError` may not be valid anymore after another received or sent message (case of `IP_COAP_NSTART > 1`).

Refer to *Sample CoAP client application* on page 995 for usage example.

**Note**

Observer result (apart from the abort) are transparent to this function. This means the return value will remain to -1 (nothing on-going) even when the observer request is completed, but the function needs to be called anyway in this case.
35.7.2.13  IP_COAP_CLIENT_GetMsgBuffer()

Description
Returns the buffer used to send messages.

Prototype
U8  *IP_COAP_CLIENT_GetMsgBuffer(IP_COAP_CLIENT_CONTEXT  *  pContext,
                                      U16                     *  pMsgLength);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>pMsgLength</td>
<td>Value to fill with the buffer length.</td>
</tr>
</tbody>
</table>

Return value
≠ NULL  Message buffer.
= NULL  Error.
35.7.2.14 IP_COAP_CLIENT_GetLocationPath()

Description
Returns the Location-Path received. This should be call when processing reply of a POST for example.

Prototype

```c
int IP_COAP_CLIENT_GetLocationPath (IP_COAP_CLIENT_CONTEXT * pContext,
                                     unsigned Index,
                                     U8 ** ppLoc,
                                     U8 * pLocLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>ppLoc</td>
<td>Pointer to place at the path start.</td>
</tr>
<tr>
<td>pLocLength</td>
<td>Value to fill with the path length.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Location-Path is present.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information
The data pointed by the location pointer will not be valid after another received or sent message.
35.7.2.15 IP_COAP_CLIENT_GetLocationQuery()

Description
Returns the Location-Query received. This should be call when processing reply of a POST for example.

Prototype

```c
int IP_COAP_CLIENT_GetLocationQuery (IP_COAP_CLIENT_CONTEXT * pContext,
                                      unsigned Index,
                                      U8 ** ppQuery,
                                      U8 * pQueryLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>ppQuery</td>
<td>Pointer to place at the query start.</td>
</tr>
<tr>
<td>pQueryLength</td>
<td>Value to fill with the Query length.</td>
</tr>
</tbody>
</table>

Return value

= IP_COAP_RETURN_OK Location-Query is present.
≠ IP_COAP_RETURN_OK Error.

Additional information

The data pointed by the query will not be valid after another message is received or sent.
35.7.2.16 IP_COAP_CLIENT_SetOptionURIPath()

**Description**

Adds the URI-Path option to a request.

**Prototype**

```c
int IP_COAP_CLIENT_SetOptionURIPath(IP_COAP_CLIENT_CONTEXT * pContext,
        unsigned Index,
        U8 * pURI,
        U8 URILength);
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pURI</td>
<td>Start of the URI-Path (without the first '/').</td>
</tr>
<tr>
<td>URILength</td>
<td>Length of the URI-Path.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK` Success.
- ≠ `IP_COAP_RETURN_OK` Error.

**Additional information**

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.

The given string for the URI-Path contains the complete URI-Path with '/' except for the first one. The break-down in many URI-Path options is done internally.
35.7.2.17  IP_COAP_CLIENT_SetOptionURIHost()

Description
Adds the URI-Host option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionURIHost(IP_COAP_CLIENT_CONTEXT * pContext,
                                     unsigned Index,
                                     U8 * pHost,
                                     U8 HostLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pHost</td>
<td>Start of the host name.</td>
</tr>
<tr>
<td>HostLength</td>
<td>Length of the host name.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  Success.
- `≠ IP_COAP_RETURN_OK`  Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.
35.7.2.18  IP_COAP_CLIENT_SetOptionURIPort()

Description
Adds the URI-Port option to a request.

Prototype

```
int IP_COAP_CLIENT_SetOptionURIPort ( IP_COAP_CLIENT_CONTEXT * pContext,
                                       unsigned Index,
                                       U16 Port);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>Port</td>
<td>URI-Port value.</td>
</tr>
</tbody>
</table>

Return value

- = IP_COAP_RETURN_OK  Success.
- ≠ IP_COAP_RETURN_OK  Error.
35.7.2.19   IP_COAP_CLIENT_SetOptionURIQuery()

Description
Adds the URI-Query option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionURIQuery(IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned                  Index,
                                          U8                        * pQuery,
                                          U8                        QueryLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pQuery</td>
<td>Start of the query.</td>
</tr>
<tr>
<td>QueryLength</td>
<td>Length of the query.</td>
</tr>
</tbody>
</table>

Return value

| = IP_COAP_RETURN_OK | Success.                                           |
| ≠ IP_COAP_RETURN_OK | Error.                                             |

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.

The given string for the URI-Query contains the complete URI-Query. The break-down in many URI-Query options is done internally using the character ‘&’ as separators.
35.7.2.20  IP_COAP_CLIENT_SetOptionETag()

Description
Adds the ETag option to a request. It’s possible to add only one ETag per request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionETag(IP_COAP_CLIENT_CONTEXT * pContext,
                                  unsigned Index,
                                  U8 * pETag,
                                  U8 ETagLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pETag</td>
<td>Start of the ETag.</td>
</tr>
<tr>
<td>ETagLength</td>
<td>Length of the ETag.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK Success.
- ≠ IP_COAP_RETURN_OK Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.
35.7.2.21  IP_COAP_CLIENT_SetOptionBlock()

Description
Adds the block option to a request. Block1 of a request is a PUT or a POST, Block2 for a GET.

Prototype

```c
int  IP_COAP_CLIENT_SetOptionBlock(IP_COAP_CLIENT_CONTEXT *  pContext,
                                  unsigned                  Index,
                                  U16                      Size);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>Size</td>
<td>Size of the block in bytes. 0 for default size.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  Success.
- `≠ IP_COAP_RETURN_OK`  Error.

Additional information

It is possible to give 0 as Size. The default block size will then be used.

Per default, GET requests don’t have the Block2 option configured. If a reply is received with blocks, then the default block size is used. This function could be used to send the request with the Block2 option already set. In case of PUT/POST, Block1 option is always added.
35.7.2.22 IP_COAP_CLIENT_SetOptionAccept()

Description
Adds the Accept option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionAccept (IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned                  Index,
                                          U16                      Value);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>Value</td>
<td>Accept format to be set in the request.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information

Some format are already defined in `IP_COAP.h` but any numerical value defined in RFCs could be used.
### 35.7.2.23  IP_COAP_CLIENT_SetOptionContentFormat()

**Description**

Adds the Content-Format option to a request.

**Prototype**

```c
int IP_COAP_CLIENT_SetOptionContentFormat (IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned Index,
                                          U16 Value);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>Value</td>
<td>Content format to be set in the request.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK`  Success.
- `~IP_COAP_RETURN_OK` Error.

**Additional information**

Some format are already defined in `IP_COAP.h` but any numerical value defined in RFCs could be used.
35.7.2.24  IP_COAP_CLIENT_SetOptionIfNoneMatch()

Description
Adds the If-None-Match option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionIfNoneMatch ( IP_COAP_CLIENT_CONTEXT * pContext,
                                        unsigned                  Index );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK  Success.
- ≠ IP_COAP_RETURN_OK  Error.
35.7.2.25  IP_COAP_CLIENT_SetOptionLocationPath()

Description
Adds the location path option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionLocationPath ( IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned Index,
                                          U8 * pLocation,
                                          U8 LocationLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pLocation</td>
<td>Pointer on the path.</td>
</tr>
<tr>
<td>LocationLength</td>
<td>Length of the path.</td>
</tr>
</tbody>
</table>

Return value

- = IP_COAP_RETURN_OK  Success.
- ≠ IP_COAP_RETURN_OK  Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.

This function is provided even though the location path option appears normally only in replies (to POST requests).

The given string for the Location-Path contains the complete Location-Path with ‘/’ except for the first one. The break-down in many Location-Path options is done internally.
35.7.2.26 IP_COAP_CLIENT_SetOptionLocationQuery()

Description

Adds the location query option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionLocationQuery(IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned Index,
                                          U8 * pQuery,
                                          U8 QueryLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pQuery</td>
<td>Pointer on the query.</td>
</tr>
<tr>
<td>QueryLength</td>
<td>Length of the query.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.

This function is provided even though the location query option appears normally only in replies (to POST requests).

The given string for the Location-Query contains the complete Location-Query. The breakdown in many Location-Query options is done internally using the character ‘&’ as separators.
35.7.2.27  IP_COAP_CLIENT_SetOptionProxyURI()

Description

Adds the proxy URI option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionProxyURI(IP_COAP_CLIENT_CONTEXT * pContext,
unsigned                  Index,
U8                     * pURI,
U16                      URILength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pURI</td>
<td>Pointer on the URI.</td>
</tr>
<tr>
<td>URILength</td>
<td>Length of the URI.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`   Success.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.
CHAPTER 35
API functions

35.7.2.28 IP_COAP_CLIENT_SetOptionProxyScheme()

Description
Adds the proxy scheme option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionProxyScheme(IP_COAP_CLIENT_CONTEXT * pContext,
                                         unsigned Index,
                                         U8 * pScheme,
                                         U8 SchemeLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pScheme</td>
<td>Pointer on the scheme.</td>
</tr>
<tr>
<td>SchemeLength</td>
<td>Length of the scheme.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- `IP_COAP_RETURN_OK` Error.

Additional information

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.
35.7.2.29 IP_COAP_CLIENT_SetOptionSize1()

Description
Adds the Size1 option to a request.

Prototype

```c
int IP_COAP_CLIENT_SetOptionSize1(IP_COAP_CLIENT_CONTEXT * pContext,
                                 unsigned Index,
                                 U32 Value);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>Value</td>
<td>Value of the Size1 option.</td>
</tr>
</tbody>
</table>

Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.
### 35.7.2.30 IP_COAP_CLIENT_SetOptionAddIFMatch()

**Description**

Adds the If-Match option to a request.

**Prototype**

```c
int IP_COAP_CLIENT_SetOptionAddIFMatch ( IP_COAP_CLIENT_CONTEXT * pContext,
                                          unsigned Index,
                                          IP_COAP_IF_MATCH_INFO * pIFMatch);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to configure.</td>
</tr>
<tr>
<td>pIFMatch</td>
<td>Parameter of the If-Match option.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK`: Success.
- `!IP_COAP_RETURN_OK`: Error.

**Additional information**

In a CoAP message, there could me many If-Match option. This option could indicate an ETag to match. It’s also possible to have a “match all” with an empty ETag. To add a “match all”, either provide a `pIFMatch` structure with the ETagLength set to 0, or give a NULL parameter as `pIFMatch`.

Only the pointer is kept, thus the passed data should be valid at least during the life of the request.

**Example**

```c
static IP_COAP_IF_MATCH_INFO IfMatch0;
static IP_COAP_IF_MATCH_INFO IfMatch1;
static IP_COAP_IF_MATCH_INFO IfMatch2;

// Send a PUT if the current ETag of "test" matches
// one of the three given ETag.
//
// IP_COAP_CLIENT_SetCommand(&_COAPClient, Index, IP_COAP_TYPE_CON, IP_COAP_CODE_REQ_PUT);
// IP_COAP_CLIENT_SetOptionURIPath(&_COAPClient, Index, "test", 4);
// IfMatch0.ETagLength = 2;
// IfMatch0.pETag = "x02\x03";
// IP_COAP_CLIENT_SetOptionAddIFMatch(&_COAPClient, Index, &IfMatch0);
// IfMatch1.ETagLength = 2;
// IfMatch1.pETag = "x01\x02";
// IP_COAP_CLIENT_SetOptionAddIFMatch(&_COAPClient, Index, &IfMatch1);
// IfMatch2.ETagLength = 2;
// IfMatch2.pETag = "x03\x03";
// IP_COAP_CLIENT_SetOptionAddIFMatch(&_COAPClient, Index, &IfMatch2);
// IP_COAP_CLIENT_SetOptionBlock(&_COAPClient, Index, 128);
// IP_COAP_CLIENT_SetPayloadHandler(&_COAPClient, Index, _PUT_Handler);
//
// IP_COAP_CLIENT_BuildAndSend(&_COAPClient, Index);
```
35.7.2.31  IP_COAP_CLIENT_OBS_Init()

Description

Initializes an observe request.

Prototype

```c
int  IP_COAP_CLIENT_OBS_Init ( IP_COAP_CLIENT_CONTEXT *  pContext ,
                                unsigned                  Index ,
                                IP_COAP_CLIENT_OBS     *  pObs ,
                                unsigned                  AutoToken );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Index of the free request to use to send the registration.</td>
</tr>
<tr>
<td>pObs</td>
<td>Observer to initializes.</td>
</tr>
<tr>
<td>AutoToken</td>
<td>Generates a token for the observe request.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.

Additional information

An observe request must have a token. Either use this simple `AutoToken` mechanism or provide a token using `IP_COAP_CLIENT_SetToken()`. Note that the `AutoToken` is based on the current time. Thus creating two observe request at the same time will generate the same token for both requests and create issues.

Example

```c
// Observe specific initialization.
//
IP_COAP_CLIENT_OBS_Init(& _COAPClient ,  Index ,  & _Observer ,  0);
IP_COAP_CLIENT_OBS_SetEndCallback(& _Observer ,  _OBS_EndHandler ,  ( void *)( U32 ) Index );
// Regular request initialization. Observe uses a GET request.
//
IP_COAP_CLIENT_SetCommand(& _COAPClient ,  Index ,  IP_COAP_TYPE_CON ,  IP_COAP_CODE_REQ_GET);
IP_COAP_CLIENT_SetOptionURIPath(& _COAPClient ,  Index ,  ( U8 *) "obs" ,  3 );
IP_COAP_CLIENT_SetOptionBlockSize(& _COAPClient ,  Index ,  16 );
IP_COAP_CLIENT_SetPayloadHandler(& _COAPClient ,  Index ,  _GET_Handler );
// Token is mandatory for an observe, so either use the AutoToken from the Init or provide one.
//
IP_COAP_CLIENT_SetToken(& _COAPClient ,  Index ,  "\x01\x02\x03\x04" ,  4 );
//
  r = IP_COAP_CLIENT_BuildAndSend(& _COAPClient ,  Index );
```
35.7.2.32 IP_COAP_CLIENT_OBS_Abort()

Description
Stops an active observer.

Prototype

```c
int IP_COAP_CLIENT_OBS_Abort ( IP_COAP_CLIENT_CONTEXT * pContext,
                                  unsigned Index,
                                  IP_COAP_CLIENT_OBS * pObs,
                                  unsigned TryActiveAbort);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Client context.</td>
</tr>
<tr>
<td>Index</td>
<td>Available request index to send the abort. Unused if TryActiveAbort is set to 0.</td>
</tr>
<tr>
<td>pObs</td>
<td>Observer to abort.</td>
</tr>
<tr>
<td>TryActiveAbort</td>
<td>Flag (0 or 1) used to prepare pObs to send a request to abort the registration.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK: Success.
- IP_COAP_RETURN_NOT_ALLOWED: Abort done, no request available for active abort.
- Other: Error.

Example

Either perform a “lazy” abort. The clients will only remove the observer from its context. When the server will send a notification, the client will automatically reply with an error.

```c
// // Abort the observe (no abort sent to the server).
// IP_COAP_CLIENT_OBS_Abort(&_COAPClient, 0 /* unused */, &_Observer, 0);
```

Or perform an active abort by sending a GET with the Observe option set to 1. The function is already setting the Observe value. Note that this abort request will be returned by IP_COAP_CLIENT_GetLastResult() contrarily to other observer related messages.

```c
// // Abort the observe indicating an abort will be sent.
// IP_COAP_CLIENT_OBS_Abort(&_COAPClient, Index, &_Observer, 1);
// // And actually send the abort reusing the on-going request.
// IP_COAP_CLIENT_SetCommand(&_COAPClient, Index, IP_COAP_TYPE_CON, IP_COAP_CODE_REQ_GET);
IP_COAP_CLIENT_SetOptionURIPath(&_COAPClient, Index, (U8*)"obs", 3);
IP_COAP_CLIENT_SetPayloadHandler(&_COAPClient, Index, _GET_Handler);
// r = IP_COAP_CLIENT_BuildAndSend(&_COAPClient, Index);
```
## 35.7.2.33 IP_COAP_CLIENT_OBS_SetEndCallback()

### Description

Configures the end callback for an observe request. This callback is called after every transfer.

### Prototype

```c
int IP_COAP_CLIENT_OBS_SetEndCallback(IP_COAP_CLIENT_OBS * pObs,
                                       PF_OBS_END_TRANSFER pfObsEndTransfer,
                                       void * pParam);
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pObs</td>
<td>Observer to configure.</td>
</tr>
<tr>
<td>pfObsEndTransfer</td>
<td>Callback called at the end of every transfer.</td>
</tr>
<tr>
<td>pParam</td>
<td>Parameter given to the callback. No internal usage.</td>
</tr>
</tbody>
</table>

### Return value

- `= IP_COAP_RETURN_OK` Success.
- `≠ IP_COAP_RETURN_OK` Error.
35.7.3 Utility

These utility functions are helper functions to check various CoAP options. They are designed to be called from the payload callbacks.
35.7.3.1   IP_COAP_CheckAcceptFormat()

Description
Verifies if the Accept-Format matches the requested one.

Prototype

```c
int IP_COAP_CheckAcceptFormat(IP_COAP_CALLBACK_PARAM * pParam,
                                  U16                      Format);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>Format</td>
<td>Requested format.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  Accept-Format option value is not present or the Accept-Format matches the requested one.
- `IP_COAP_RETURN_ERR` Accept-Format option doesn’t match.
35.7.3.2  IP_COAP_GetAcceptFormat()

Description
Reads the Accept-Format option value.

Prototype

```
int  IP_COAP_GetAcceptFormat(IP_COAP_CALLBACK_PARAM * pParam,
                               U16                    * pFormat);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pFormat</td>
<td>Variable to store the Accept-Format value.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**  Accept-Format option value is present and set in `pFormat`.
- **IP_COAP_RETURN_ERR** Accept-Format option not present.
35.7.3.3  IP_COAP_CheckContentFormat()

Description
Verifies if the Content-Format match the requested one.

Prototype

```c
int IP_COAP_CheckContentFormat(IP_COAP_CALLBACK_PARAM * pParam,
                               U16                      Format,
                               unsigned                  OptionMandatory);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>Format</td>
<td>Requested Content-Format.</td>
</tr>
<tr>
<td>OptionMandatory</td>
<td>Flag to indicate if the presence of the Content-Format option is mandatory or not.</td>
</tr>
<tr>
<td></td>
<td>• 1: Mandatory.</td>
</tr>
<tr>
<td></td>
<td>• 0: Optional.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**: The option format matches the requested one or the option is not present (and the flag OptionMandatory is 0).
- **IP_COAP_RETURN_OPTION_ERROR**: Option is not present (OptionMandatory is 1)
- **IP_COAP_RETURN_ERR**: Content-Format doesn't match the requested one.
35.7.3.4   IP_COAP_GetContentFormat()

Description
Reads the Content-Format option value.

Prototype

```c
int IP_COAP_GetContentFormat (IP_COAP_CALLBACK_PARAM * pParam,
                               U16 * pFormat);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pFormat</td>
<td>Variable to store the Content-Format value.</td>
</tr>
</tbody>
</table>

Return value

- IP_COAP_RETURN_OK  Content-Format option value is present and set in `pFormat`
- IP_COAP_RETURN_ERR Content-Format option not present.
35.7.3.5 IP_COAP_IsLastBlock()

Description
Checks if the current block is the last one of the transfer.

Prototype

```
int IP_COAP_IsLastBlock(IP_COAP_CALLBACK_PARAM * pParam,
                        U8 Code);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>Code</td>
<td>Code of the procedure</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_GET</td>
</tr>
<tr>
<td></td>
<td>• IP_COAP_CODE_REQ_PUT / IP_COAP_CODE_REQ_POST</td>
</tr>
</tbody>
</table>

Return value
1       This is the last block (or no block transfer)
0       More blocks are expected.

Additional information
If the procedure is a GET, Block2 is checked. Otherwise Block1 is checked.
35.7.3.6 IP_COAP_GetURIHost()

Description
Sets a pointer on the start of the URI-HostName.

Prototype

```c
int IP_COAP_GetURIHost(IP_COAP_CALLBACK_PARAM * pParam,
                       U8 ** ppHost,
                       U8 * pHostLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppHost</td>
<td>Address of the pointer where the HostName starts.</td>
</tr>
<tr>
<td>pHostLength</td>
<td>To be filled with the actual Host length.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`: URI-Host option is present and `ppHost`, `pHostLength` are updated.
- `IP_COAP_RETURN_ERR`: URI-Host option not present.

Additional information

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
35.7.3.7  IP_COAP_GetURIPath()

Description
Sets a pointer on the start of the URI-Path.

Prototype

```c
int IP_COAP_GetURIPath(IP_COAP_CALLBACK_PARAM * pParam,
                        U8 ** ppURI,
                        U8 * pURILength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppURI</td>
<td>Address of the pointer where the URI starts.</td>
</tr>
<tr>
<td>pURILength</td>
<td>To be filled with the actual URI length.</td>
</tr>
</tbody>
</table>

Return value

- `IP_COAP_RETURN_OK`  URI-Path option is present and `ppURI`, `pURILength` are updated.
- `IP_COAP_RETURN_ERR` URI-Path option not present.

Additional information

It makes only sense to be used by the server. In this case, the URI is re-assembled with ‘/’ (the first one is omitted). For example if two URI-Path options are present with “sensor” and “temp”, the returned string will be “sensor/temp”.

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
35.7.3.8 IP_COAP_GetURIPort()

**Description**
Reads the URI-Port option value.

**Prototype**

```c
int IP_COAP_GetURIPort(IP_COAP_CALLBACK_PARAM * pParam,
                        U16                * pURIPort);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pURIPort</td>
<td>Variable to store the URI-Port value.</td>
</tr>
</tbody>
</table>

**Return value**

- `IP_COAP_RETURN_OK` : URI-Port option value is present and set in `pURIPort`.
- `IP_COAP_RETURN_ERR` : URI-Port option not present.
35.7.3.9  IP_COAP_GetQuery()

Description
Sets a pointer on the start of the Query field.

Prototype

```c
int IP_COAP_GetQuery(IP_COAP_CALLBACK_PARAM * pParam,
                      U8 ** ppQuery,
                      U16 * pQueryLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppQuery</td>
<td>Address of the pointer where the Query starts.</td>
</tr>
<tr>
<td>pQueryLength</td>
<td>To be filled with the actual Query length.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**  Query option is present and `ppQuery`, `pQueryLength` are updated.
- **IP_COAP_RETURN_ERR** Query option not present.

Additional information

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
35.7.3.10 IP_COAP_GetETag()

Description
Sets a pointer on the ETag value.

Prototype

```c
int IP_COAP_GetETag(IP_COAP_CALLBACK_PARAM * pParam,
                     U8 ** ppETag,
                     U8 * pETagLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppETag</td>
<td>Address of the pointer where the ETag starts.</td>
</tr>
<tr>
<td>pETagLength</td>
<td>To be filled with the actual ETag length.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**: ETag option is present and `ppETag`, `pETagLength` are updated.
- **IP_COAP_return_ERR**: ETag option not present.

Additional information

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
35.7.3.11  IP_COAP_GetMaxAge()

Description
Reads the MaxAge option value.

Prototype

```c
int IP_COAP_GetMaxAge(IP_COAP_CALLBACK_PARAM * pParam,
U32 * pMaxAge);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pMaxAge</td>
<td>Variable to store the MaxAge value.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**: MaxAge option value is present and set in `pMaxAge`.
- **IP_COAP_RETURN_ERR**: MaxAge option not present.
35.7.3.12 IP_COAP_GetSize1()

**Description**
Reads the Size1 option value.

**Prototype**

```c
int IP_COAP_GetSize1(IP_COAP_CALLBACK_PARAM * pParam,
                     U32 * pSize1);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pSize1</td>
<td>Variable to store the Size1 value.</td>
</tr>
</tbody>
</table>

**Return value**

- IP_COAP_RETURN_OK: Size1 option value is present and set in pSize1.
- IP_COAP_RETURN_ERR: Size1 option not present.
35.7.3.13   **IP_COAPGetSize2()**

**Description**
Reads the Size2 option value.

**Prototype**

```c
int IP_COAPGetSize2(IP_COAP_CALLBACK_PARAM * pParam,
                    U32            * pSize2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>pSize2</td>
<td>Variable to store the Size2 value.</td>
</tr>
</tbody>
</table>

**Return value**

- **IP_COAP_RETURN_OK**: Size2 option value is present and set in `pSize2`.
- **IP_COAP_RETURN_ERR**: Size2 option not present.
35.7.3.14 IP_COAP_GetLocationPath()

Description
Sets a pointer on the start of the Location-Path.

Prototype

```c
int IP_COAP_GetLocationPath(IP_COAP_CALLBACK_PARAM * pParam,
    U8 ** ppLoc,
    U8 * pLocLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppLoc</td>
<td>Address of the pointer where the location starts.</td>
</tr>
<tr>
<td>pLocLength</td>
<td>To be filled with the actual URI length.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK** Location option is present and `ppLoc`, `pLocLength` are updated.
- **IP_COAP_RETURN_ERR** Location option not present.

Additional information

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
35.7.3.15  IP_COAP_GetLocationQuery()

Description
Sets a pointer on the start of the Location-Query field.

Prototype

```c
int IP_COAP_GetLocationQuery(IP_COAP_CALLBACK_PARAM * pParam,
                              U8 ** ppQuery,
                              U16 * pQueryLength);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pParam</td>
<td>Pointer on the callback’s parameter structure.</td>
</tr>
<tr>
<td>ppQuery</td>
<td>Address of the pointer where the Query starts.</td>
</tr>
<tr>
<td>pQueryLength</td>
<td>To be filled with the actual Query length.</td>
</tr>
</tbody>
</table>

Return value

- **IP_COAP_RETURN_OK**  
  Query option is present and `ppQuery`, `pQueryLength` are updated.
- **IP_COAP_RETURN_ERR**  
  Query option not present.

Additional information

If you plan on using the string later, make a copy of it as the pointer won’t be valid after the callbacks.
### 35.8 Data structures

</tbody>
</table>
35.8.1 Structure IP_COAP_SERVER_CONTEXT

Description
Main context of the server.

Prototype

```c
struct {  
// // Buffer for the UDP packet handling (Rx/Tx).  
// U8*  pMsgBuffer;  
U16   MsgBufferSize;  
// // APIs for UDP transmission and time.  
// int (*pfReceive) (U8* pBuffer,  
unsigned BufferSize,  
IP_COAP_CONN_INFO* pInfo,  
unsigned* pIsMulticast);  
int (*pfSend) (U8* pBuffer,  
unsigned BufferSize,  
IP_COAP_CONN_INFO* pInfo);  
U32 (*pfGetTimeMs) (void);  
// // Server parameters.  
// const char* sHostName;  
const char* sErrorMsg;  
IP_COAP_SERVER_DATA* pFirstData;  
IP_COAP_SERVER_DATA DataWellKnownCore;  
// // IP_COAP_SERVER_CLIENT_INFO* pFirstClient;  
// // IP_COAP_SERVER_CLIENT_INFO* pFreeClient;  
// // IP_COAP_OBSERVER* pFirstObs;  
// // IP_COAP_OBSERVER* pFreeObs;  
// // PF_POST_HANDLER pfPOSTCreateEntry;  
// // Internal data.  
// IP_COAP_SERVER_DATA* pDataFirstFound;  
U8* pPayload;  
U32 OptionMask;  
U16 UDPPort;  
U16 PayloadLength;  
U16 StructureETag;  
U16 URILengthReq;  
U16 MsgLength;  
U16 BadOption;  
U16 MessageId;  
U8 DefaultSzx;  
U8 ConfigMask;  
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pMsgBuffer</td>
<td>Buffer used to receive and send CoAP messages in UDP. Initialized in IP_COAP_SERVER_Init()</td>
</tr>
<tr>
<td>MsgBufferSize</td>
<td>Size of the message buffer.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Callback to receive UDP packets (see Callback pfReceive on page 1095)</td>
</tr>
</tbody>
</table>
### Member | Description
--- | ---
pfSend | Callback to send UDP packets (see *Callback* `pfSend` on page 1095).
pfGetTimeMs | Callback to get the current time in milliseconds (see *Callback* `pfGetTimeMs` on page 1095).
sHostName | If it is requested to send the Uri-Host option by a `IP_COAP_SERVER_DATA`, the hostname used is this one. (initialized to a null pointer). All resources associated to a server are using the same host name. This is a null terminated string.
sErrorDesc | Null terminated string sent in an error message.
pFirstData | Start of the linked list of server resources. Used by `IP_COAP_SERVER_AddData()` and `IP_COAP_SERVER_RemoveData()`.
DataWellKnownCore | Resource used to reply to a discover (GET `.well-known/core`). This will automatically return the list of all resources of the server with the CoRE format.
pFirstClient | Start of the linked list of the currently connected clients. Internal usage only.
pFreeClient | Linked list of the client structure pool. Initialized with `IP_COAP_SERVER_AddClientBuffer()`.
pFirstObs | Start of the linked list of the currently connected observers. Internal usage only.
pFreeObs | Linked list of the observer structure pool. Initialized with `IP_COAP_SERVER_AddObserverBuffer()`.
pfPOSTCreateEntry | Call back used to create a new entry when getting a POST command. Initialized with `IP_COAP_SERVER_SetPOSTHandler()`. If left unset (NULL), the server won't allow the creation of new resource entries and will automatically reply with a 4.05 Method Not Allowed.
UDPPort | If it is requested to send the Uri-Port option by a `IP_COAP_SERVER_DATA`, the port used is this one (initialized to the default port). All resources associated to a server are using the same port.

### Additional information

The fields of this structure should be set only via APIs or internal functions.

A client pool is given to the server with the function `IP_COAP_SERVER_AddClientBuffer()`. The size of this pool defines the number of clients connected to the server at the same time. The server could handle more clients as the connections are closed once data transfers are completed. Thus a buffer of at least one client is mandatory but even in this case, many more actual clients could be served especially if there are no long block transfers and CON is used to mitigate congestions.

An observer pool is given to the server with the function `IP_COAP_SERVER_AddObserverBuffer()`. The size of this pool defines the number of observers handled by the server at the same time. It could be null if no observable resources are configured.
35.8.2 Structure IP_COAP_SERVER_DATA

Description
Server context to describe a resource.

Prototype

```c
struct IP_COAP_SERVER_DATA_STRUCT {
    IP_COAP_SERVER_DATA* pNext;
    //
    const char* sURI;
    const char* sDescription;
    U8 ETag[8];
    U32 MaxAge;
    U32 Size2;
    U32 DefGetOptMask;
    U16 ContentFormat;
    U8 ETagLength;
    U8 ObsConfig;
    //
    // Callbacks to handle the requests.
    //
    int (*pfGETPayload)(IP_COAP_SERVER_CONTEXT* pContext,
                        U8** ppBuffer,
                        U16* pLength,
                        IP_COAP_CALLBACK_PARAM* pParam);
    int (*pfPUTPayload)(IP_COAP_SERVER_CONTEXT* pContext,
                        U8* pPayload,
                        U16 Length,
                        IP_COAP_CALLBACK_PARAM* pParam);
    int (*pfDELHandler)(IP_COAP_SERVER_CONTEXT* pContext,
                        IP_COAP_CALLBACK_PARAM* pParam);
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Anchor for the linked list. Internal use only.</td>
</tr>
<tr>
<td>sURI</td>
<td>Null terminated string for the resource Uri-Path. The first '/' is omitted.</td>
</tr>
<tr>
<td>sDescription</td>
<td>Null terminated string for the description of the resource in CoRE format. If the resource is an observable, “obs” is automatically added and should not be set here.</td>
</tr>
<tr>
<td>ETag</td>
<td>entity-tag (ETag) of the resource.</td>
</tr>
<tr>
<td>MaxAge</td>
<td>MaxAge (value validity) duration of a the resource after a GET.</td>
</tr>
<tr>
<td>Size2</td>
<td>Size of the resource sent in a GET reply if configured so.</td>
</tr>
<tr>
<td>DefGetOptMask</td>
<td>Default options characterizing the resource sent in a GET reply (see below).</td>
</tr>
<tr>
<td>ContentFormat</td>
<td>Content-Format of the resource. Some format are defined in the RFC and are in IP_COAP.h (IP_COAP_CT_xxx) but other numerical values could be used.</td>
</tr>
<tr>
<td>ETagLength</td>
<td>Length of ETag.</td>
</tr>
<tr>
<td>ObsConfig</td>
<td>Configuration of the observe parameters of the resource (see below). Set to 0 if the resource is not observable.</td>
</tr>
<tr>
<td>pfGETPayload</td>
<td>Callback used to fill the payload when replying to a GET (see pfGETPayload). If set to NULL, the server will reply with a 4.05 Not Allowed when receiving the request.</td>
</tr>
</tbody>
</table>
### Chapter 35: Data structures

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfPUTPayload</td>
<td>Callback used to handle the payload when receiving a PUT or POST (see pfPUTPayload). If set to NULL, the server will reply with a 4.05 Not Allowed when receiving the request.</td>
</tr>
<tr>
<td>pfDELEHandler</td>
<td>Callback used to check the authorization of a DELETE request (see pfDELEHandler). If set to NULL, the server will reply with a 4.05 Not Allowed when receiving the request.</td>
</tr>
</tbody>
</table>

**Additional information**

This structure should be initialized with 0 (memset) and then configured before being added to the server with the function IP_COAP_SERVER_AddData().

The DefGetOptMask describes which options should be sent by default in a GET reply to inform the client. The mask format is defined by IP_COAP_OPTMASK_xxx defines. The possible options to set in this define are:

- **IP_COAP_OPTMASK_ETAG**: Send the entity-tag of the resource. ETag and ETagLength should be correctly set.
- **IP_COAP_OPTMASK_URI_PORT**: Send the UDP Port used to communicate with the resource. UDPPort of the server context IP_COAP_SERVER_CONTEXT should be correctly set.
- **IP_COAP_OPTMASK_URI_HOST**: Send the Uri-Host of the resource. sHostName of the server context IP_COAP_SERVER_CONTEXT should be correctly set.
- **IP_COAP_OPTMASK_CONTENT_FORMAT**: Send the content-format of the resource. ContentFormat should be correctly set.
- **IP_COAP_OPTMASK_MAX_AGE**: Send the max-age of the resource (validity time) in seconds. MaxAge should be correctly set.
- **IP_COAP_OPTMASK_SIZE2**: Send the data length of the resource (approximated value). This could be used by the client in case of block transfer. Size2 should be correctly set.

The observe configuration in ObsConfig is also a mask using the define IP_COAP_OBS_xxx. The bit IP_COAP_OBS_OBSERVABLE should always be set to indicate the resource is observable. It is possible to optionally configure either IP_COAP_OBS_AUTO_CON_ON_MAX_AGE or IP_COAP_OBS_AUTO_NON_ON_MAX_AGE. The server will then automatically send a notification (either CON or NON) every MaxAge seconds. For example, it is possible to send a NON notification at every MaxAge expiry and a CON notification when the value is actually changed (by calling IP_COAP_SERVER_UpdateData()).

**Example**

```c
pServerData = & _COAPServerData[0];
IP_COAP_MEMSET(pServerData, 0, sizeof(IP_COAP_SERVER_DATA));
// URI-Path with the first '/' omitted.
//
pServerData->sURI = "temperature/meas";
// Description: optional and could be set to NULL. Follows the CoRE format.
// "obs" is added automatically is the resource is defined as observable.
//
pServerData->sDescription = "ct=0;title="Temperature measurement done every 2 minutes";"
// Callback to perform GET and PUT. DELETE is disabled as the callback
// is not set.
//
pServerData->pfGETPayload = _Temperature_Meas1_GetPayload;
pServerData->pfPUTPayload = _Temperature_Meas1_PutPayload;
// Default content format is plain/text.
//
pServerData->ContentFormat = IP_COAP_CT_TXT;
```
// Configure an ETag.
//
IP_COAP_MEMCPY(pServerData->ETag, "\x01\x02\x03\x04\x05\x06\x07\x08", 8);
pServerData->ETagLength = 8;

// Data are valid for 2 minutes.
//
pServerData->MaxAge = 120;

// data size is approximately 8 bytes long.
//
pServerData->Size2 = 8;

// In a reply to a GET, send the options: ETag, Content-Format, Max-Age and Size2.
//
pServerData->DefGetOptMask = IP_COAP_OPTMASK_ETAG | IP_COAP_OPTMASK_CONTENT_FORMAT | IP_COAP_OPTMASK_MAX_AGE | IP_COAP_OPTMASK_SIZE2;

// This resource is observable. Server will send a NON at Max-Age period.
//
pServerData->ObsConfig = IP_COAP_OBS_OBSERVABLE | IP_COAP_OBS_AUTO_NON_ON_MAX_AGE;
35.8.3 Callback PF_POST_HANDLER

Description
Server callback to create a new resource when receiving a POST.

Prototype

```c
typedef int (*PF_POST_HANDLER)(IP_COAP_SERVER_CONTEXT* pContext,
                               IP_COAP_CALLBACK_PARAM* pParam,
                               U32 PayloadLength,
                               IP_COAP_SERVER_DATA** ppServerData);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the server context.</td>
</tr>
<tr>
<td>pParam</td>
<td>Parameter structure. See IP_COAP_CALLBACK_PARAM.</td>
</tr>
<tr>
<td>PayloadLength</td>
<td>Indication on the payload length. It is either the Size1 parameter if given or the length of the 1st block.</td>
</tr>
<tr>
<td>ppServerData</td>
<td>Receives the created IP_COAP_SERVER_DATA. Don’t call IP_COAP_SERVER_AddData() as it will be done by the server if the pointer is set.</td>
</tr>
</tbody>
</table>

Additional information

The return values are of type IP_COAP_RETURN. The possible values are:

- IP_COAP_RETURN_OK: Entry created.
- Any one of the defined error return values. If an error is returned, it could be usefull for the operator to add a short description (null-terminated string) that would be appended to the error message.

The actual payload will be handle by the PUT payload handler (pfPUTPayload) of the newly created resource. If an error happens the resource will be removed from the server context.

Example

```c
static int _POSTCreateEntry(IP_COAP_SERVER_CONTEXT* pContext, IP_COAP_CALLBACK_PARAM* pParam,
                             U32 PayloadLength, IP_COAP_SERVER_DATA** ppServerData) {
    U8* pURI;
    U8 Length;

    // Check the validity of the POST request.
    if (POST_Is_Authorized) {
        IP_COAP_SERVER_SetErrorDescription(pContext, "Client not authorized");
        return IP_COAP_RETURN_NOT_ALLOWED;
    }

    // if (PayloadLength > POST_DATA_LENGTH) {
    //     IP_COAP_SERVER_SetErrorDescription(pContext, "Maximum size is 128 bytes");
    //     return IP_COAP_RETURN_BUFFER_TOO_SMALL;
    // }

    if (IP_COAP_GetURIPath(pParam, &pURI, &Length) != IP_COAP_RETURN_OK) {
        return IP_COAP_RETURN_ERR;
    }

    // if (Length >= 64) {
    //     IP_COAP_SERVER_SetErrorDescription(pContext, "Maximum URI path is 64 long");
    //     return IP_COAP_RETURN_BUFFER_TOO_SMALL;
    // }

    // Create the new data.
    // 1. Copy the Uri-Path in a static string.
```
IP_COAP_MEMCPY(& _POSTUriPath[0], pURI, Length);
_POSTUriPath[Length] = 0; // Terminate the string with a '0'.

// 2. Initialize the new resource.

IP_COAP_MEMSET(& _ServerData, 0, sizeof(IP_COAP_SERVER_CLIENT_INFO));
_POSTServerData.sURI = & _POSTUriPath[0];
_POSTServerData.sDescription = "title=""User created entry"""";
_POSTServerData.pfGETPayload = _POSTCreateEntry_GetPayload;
_POSTServerData.pfPUTPayload = _POSTCreateEntry_PutPayload;
_POSTServerData.pfDELHandler = _POSTCreateEntry_DelHandler;

// 3. Set the ServerData pointer. Don't call IP_COAP_SERVER_AddData(), it is done
// by the server automatically.

*ppServerData = & _POSTServerData;

return IP_COAP_RETURN_OK;
}
35.8.4 Callback pfGETPayload

Description
Server data callback to fill the payload of a GET request.

Prototype

```c
int (*pfGETPayload)(IP_COAP_SERVER_CONTEXT* pContext, U8** ppBuffer, U16* pLength, IP_COAP_CALLBACK_PARAM* pParam);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the server context.</td>
</tr>
<tr>
<td>ppBuffer</td>
<td>Start of the payload location. To be moved to the end of the copied data.</td>
</tr>
<tr>
<td>pLength</td>
<td>Length of the remaining bytes in the message/block. To be reduced from the</td>
</tr>
<tr>
<td></td>
<td>number of added data.</td>
</tr>
<tr>
<td>pParam</td>
<td>Callback parameters. Refer to IP_COAP_CALLBACK_PARAM.</td>
</tr>
</tbody>
</table>

Additional information

The callback parameter contains information regarding the request, especially the block information.

The return values are of type IP_COAP_RETURN. The possible values are:

- **IP_COAP_RETURN_SEND_END**: The payload is added and this is the last block (or no block used).
- **IP_COAP_RETURN_SEND_SEPARATE**: The data are not ready, send an ACK. IP_COAP_SERVER_UpdateData() will be called later to reply to the client with a new request.
- **IP_COAP_RETURN_SEND_BLOCK**: The payload is added but there are more data to copy. The block should be fully filled.
- Any one of the defined error return values. If an error is returned, it could be useful for the operator to add a short description (null-terminated string) that would be appended to the error message.

**Note:** There are two other possible return values:

- **IP_COAP_RETURN_IGNORE_BLOCK** and **IP_COAP_RETURN_IGNORE_END**: These have the same behavior as **IP_COAP_RETURN_SEND_BLOCK** and **IP_COAP_RETURN_SEND_END**, but the server won’t send the message currently built. It is up to the application to build and send the complete CoAP message on its own. It shouldn’t be needed to use them.

Example

First example with a simple short data (no block). The data needs some time to be computed and thus sends a separate reply (first send a simple ACK and when the data is ready the application have to call IP_COAP_SERVER_UpdateData() which will call the callback again to send the reply).

```c
static int _GetPayload(IP_COAP_SERVER_CONTEXT* pContext, U8** ppBuffer, U16* pLength, IP_COAP_CALLBACK_PARAM* pParam) {
    U8* pBuffer;
    U16 Length;
    int r;

    pContext;

    if (IP_COAP_CheckAcceptFormat(pParam, IP_COAP_CT_TXT) != IP_COAP_RETURN_OK) {
        IP_COAP_SERVER_SetErrorDescription(pContext, "plain/text only");
        return IP_COAP_RETURN_CT_FORMAT_ERROR;
    }
```
Second example with block support. The resource data is in `_Data` and its length is in `_DataLength`. Reply is piggybacked with the ACK.

```c
static int _GetPayload (IP_COAP_SERVER_CONTEXT * pContext, U8 ** ppBuffer, U16 * pLength, IP_COAP_CALLBACK_PARAM * pParam) {
    U8 * pBuffer;
    U16 Length;
    int Offset;
    int Len;
    int r;

    (void)pContext;

    if (IP_COAP_CheckAcceptFormat(pParam, IP_COAP_CT_TXT) != IP_COAP_RETURN_OK) {
        IP_COAP_SERVER_SetErrorDescription(pContext, "plain/text only");
        return IP_COAP_RETURN_CT_FORMAT_ERROR;
    }

    pBuffer = *ppBuffer;
    Length = *pLength;
    r = IP_COAP_RETURN_SEND_BLOCK; // By default indicates there are more data.
    Len = Length;

    if (pParam->pBlock != NULL) {
        Offset = pParam->pBlock->Index * pParam->pBlock->Size;
    } else {
        Offset = 0;
    }

    if (Offset >= _DataLength) {
        return IP_COAP_RETURN_NO_PAYLOAD;
    }

    if ((Offset + Len) >= _DataLength) {
        // Last block of the transfer.
        Len = _DataLength - Offset;
        r = IP_COAP_RETURN_SEND_END;
    }

    IP_COAP_MEMCPY (pBuffer, _Data + Offset, Len);
    pBuffer += Len;
    Length -= Len;

    *ppBuffer = pBuffer;
    *pLength = Length;

    return r;
}
```
*pLength = Length;
return r;
35.8.5 Callback pfPUTPayload

Description
Server data callback to store the payload of a PUT request.

Prototype

```c
int (*pfPUTPayload)(IP_COAP_SERVER_CONTEXT* pContext,
U8* pPayload,
U16 Length,
IP_COAP_CALLBACK_PARAM* pParam);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the server context.</td>
</tr>
<tr>
<td>pPayload</td>
<td>Start of the payload memory.</td>
</tr>
<tr>
<td>Length</td>
<td>Length of the payload.</td>
</tr>
<tr>
<td>pParam</td>
<td>Callback parameters. Refer to IP_COAP_CALLBACK_PARAM.</td>
</tr>
</tbody>
</table>

Additional information
The callback parameter contains information regarding the request, especially the block information.

The return values are of type IP_COAP_RETURN. The possible values are:
- IP_COAP_RETURN_OK: The resource is updated with the received data block.
- Any one of the defined error return values. If an error is returned, it could be useful for the operator to add a short description (null-terminated string) that would be appended to the error message. For example IP_COAP_RETURN_NO_PAYLOAD will trigger an error “4.08 Request Entity Incomplete”.

Example
The first example is a short data (no block support) accepting either plain/text or application/octet-stream.

```c
static int _PutPayload(IP_COAP_SERVER_CONTEXT* pContext, U8* pPayload,
U16 Length, IP_COAP_CALLBACK_PARAM* pParam) {
    int r;
    U16 Format;

    if (Length == 0) {
        return IP_COAP_RETURN_ERR;
    }
    if (pParam->pBlock != NULL) {
        if (pParam->pBlock->Index > 0) {
            IP_COAP_SERVER_SetErrorDescription(pContext, "Block transfer not supported");
            return IP_COAP_RETURN_ERR;
        }
    }
    // Check if there is a content format specified.
    if (IP_COAP_GetContentFormat(pParam, &Format) != IP_COAP_RETURN_OK) {
        // Assume plain/text by default if Content-Format option is not set.
        Format = IP_COAP_CT_TXT;
    }
    if (Format == IP_COAP_CT_TXT) {
        // Format plain/text.
        r = _ParseString(pPayload, Length);
    }
    return r;
}
```
if (r != 0) {
    IP_COAP_SERVER_SetErrorDescription(pContext, "Invalid string format");
    return IP_COAP_RETURN_ERR;
} else if (Format == IP_COAP_CT_OCTET_STREAM) {
    // Format binary.
    r = _ParseBinary(pPayload, Length);
    if (r != 0) {
        IP_COAP_SERVER_SetErrorDescription(pContext, "Invalid binary format");
        return IP_COAP_RETURN_ERR;
    } else {
        IP_COAP_SERVER_SetErrorDescription(pContext, "Accept either plain/text or octet-stream");
        return IP_COAP_RETURN_CT_FORMAT_ERROR;
    }
    return IP_COAP_RETURN_OK;
}

Other example with block support.

static int _PutPayload(IP_COAP_SERVER_CONTEXT * pContext, U8 * pPayload,
                       U16 Length, IP_COAP_CALLBACK_PARAM * pParam) {
    int Offset;
    // Request that content format is present and of type plain/text.
    // if (IP_COAP_CheckContentFormat(pParam, IP_COAP_CT_TXT, 1) != IP_COAP_RETURN_OK) {
    //    IP_COAP_SERVER_SetErrorDescription(pContext, "Content Format plain/text requested");
    //    return IP_COAP_RETURN_CT_FORMAT_ERROR;
    //}
    if (pParam->pBlock != NULL) {
        Offset = pParam->pBlock->Index * pParam->pBlock->Size;
    } else {
        Offset = 0;
    }
    // if (Offset >= 128) {
    //    return IP_COAP_RETURN_BUFFER_TOO_SMALL;
    //}
    if ((Offset + Length) > 128) {
        return IP_COAP_RETURN_BUFFER_TOO_SMALL;
    }
    IP_COAP_MEMCPY(_Data + Offset, pPayload, Length);
    // Check if this is the end of the transfer.
    // if (IP_COAP_IsLastBlock(pParam, IP_COAP_CODE_REQ_PUT) != 0) {
    //    _FinishDataUpdate();
    //}
    return IP_COAP_RETURN_OK;
}
35.8.6 Callback pfDELHandler

Description
Server data callback to check the authorization to perform a DELETE request.

Prototype

```c
int (*pfDELHandler)(IP_COAP_SERVER_CONTEXT* pContext,
                   IP_COAP_CALLBACK_PARAM* pParam);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer to the server context.</td>
</tr>
<tr>
<td>pParam</td>
<td>Callback parameters. Refer to IP_COAP_CALLBACK_PARAM.</td>
</tr>
</tbody>
</table>

Additional information
The callback parameter contains information regarding the request, especially the client UDP connection info.

The return values are of type IP_COAP_RETURN. The possible values are:

- **IP_COAP_RETURN_OK**: The resource is deleted. Do not call IP_COAP_SERVER_RemoveData(). It will be done by the server.
- **IP_COAP_RETURN_OK_NO_DELETE**: The server will reply with a 2.02 Deleted but will not actually remove the data (no call to IP_COAP_SERVER_RemoveData()).
- Any one of the defined error return values. If an error is returned, it could be useful for the operator to add a short description (null-terminated string) that would be appended to the error message.

Example

```c
static int _DelHandler(IP_COAP_SERVER_CONTEXT* pContext, IP_COAP_CALLBACK_PARAM* pParam) {
    (void)pContext;

    if (_IsDeleteAuthorized(pParam->pConnInfo) == 0) {
        return IP_COAP_RETURN_NOT_ALLOWED;
    }
    //
    // Data will be deleted, free some memory.
    //
    _FreeData();

    return IP_COAP_RETURN_OK;
}
```
35.8.7 Structure IP_COAP_CLIENT_CONTEXT

Description

Main context of the client. A client is dedicated to a server. If it is needed to have activities with two servers during the same period of time, then two clients are needed.

Prototype

```
struct {
    //
    // Buffer for the UDP packet handling (Rx/Tx).
    //
    U8* pMsgBuffer;
    U16 MsgBufferSize;
    //
    // UDP transmission function.
    //
    int (*pfReceive) (U8* pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO* pInfo, unsigned* pIsMulticast);
    int (*pfSend) (U8* pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO* pInfo);
    U32 (*pfGetTimeMs)(void);
    //
    // Client parameters.
    //
    IP_COAP_CLIENT_REQUEST aRequest [IP_COAP_NSTART];
    IP_COAP_CONN_INFO ConnInfo;
    IP_COAP_CLIENT_OBS* pFirstObs;
    //
    // Internal data.
    //
    U8* pPayload;
    U16 PayloadLength;
    U16 MessageId;
    U8 DefaultSzx;
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pMsgBuffer</td>
<td>Buffer used to receive and send CoAP messages in UDP. Initialized in IP_COAP_CLIENT_Init()</td>
</tr>
<tr>
<td>MsgBufferSize</td>
<td>Size of the message buffer.</td>
</tr>
<tr>
<td>pfReceive</td>
<td>Callback to receive UDP packets (see Callback pfReceive on page 1095)</td>
</tr>
<tr>
<td>pfSend</td>
<td>Callback to send UDP packets (see Callback pfSend on page 1095)</td>
</tr>
<tr>
<td>pfGetTimeMs</td>
<td>Callback to get the current time in milliseconds (see Callback pfGetTimeMs on page 1095).</td>
</tr>
<tr>
<td>aRequest</td>
<td>Structure used to describe a request to the server.</td>
</tr>
<tr>
<td>ConnInfo</td>
<td>UDP connection information of the server. Set by calling IP_COAP_CLIENT_SetServerAddress().</td>
</tr>
<tr>
<td>pFirstObs</td>
<td>Start of the linked list of the active observers. Modified through IP_COAP_CLIENT_OBS_Init() and IP_COAP_CLIENT_OBS_Abort().</td>
</tr>
</tbody>
</table>

Additional information

This structure shouldn’t be directly modified. Only APIs should be used.
35.8.8 Callback PF_OBS_END_TRANSFER

Description
Observer end-of-transfer indication. This function is called by the client process whenever a notification from an observed data is totally received.

Prototype

```c
typedef void ( * PF_OBS_END_TRANSFER ) ( U8 Code , int IsFinal , void * pParam );
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>CoAP code of the received notification.</td>
</tr>
<tr>
<td>IsFinal</td>
<td>Indication that the server canceled the observe, either because of some errors or because the server didn’t reply with the observe option.</td>
</tr>
<tr>
<td>pParam</td>
<td>Parameter given to the function IP_COAP_CLIENT_OBS_SetEndCallback(). It is unused by the the client process (application usage only).</td>
</tr>
</tbody>
</table>

Additional information
The server may “lose” the observer information without informing the client (due to loss of packets for example). This is the role of the application to refresh the observe registration if no notification is received for some time.
35.8.9 Callback PF_CLIENT_PAYLOAD

Description
Client callback to handle the payload of GET/PUT.

Prototype

```c
typedef int (*PF_CLIENT_PAYLOAD)(IP_COAP_CLIENT_CONTEXT* pContext,
                                 U8 ** ppPayload,
                                 U16* pLength,
                                 IP_COAP_CALLBACK_PARAM* pParam);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>Pointer on the server context.</td>
</tr>
<tr>
<td>ppBuffer</td>
<td>Start of the payload location. To be moved to the end of the copied data.</td>
</tr>
<tr>
<td>pLength</td>
<td>Length of the remaining bytes in the message/block. To be reduced from the number of added data.</td>
</tr>
<tr>
<td>pParam</td>
<td>Callback parameters. Refer to IP_COAP_CALLBACK_PARAM.</td>
</tr>
</tbody>
</table>

Additional information

The return values are of type IP_COAP_RETURN. The possible values are:

- **IP_COAP_RETURN_SEND_END**: The payload is added to PUT or POST request and this is the last block (or no block used).
- **IP_COAP_RETURN_SEND_BLOCK**: The payload is added to PUT or POST request and there are more data to copy. The block should be fully filled.
- **IP_COAP_RETURN_NO_PAYLOAD**: For some reason, there are no payload to copy.
- **IP_COAP_RETURN_OK**: The payload from a GET reply is handled.
- Any one of the defined error return values. If an error is returned, it could be useful for the operator to add a short description (null-terminated string) that would be appended to the error message.

Examples

This first example is a callback for a GET request. The callback will be called when the response with the content is received. Separate responses are transparent for the client.

```c
static int _GET_Handler(IP_COAP_CLIENT_CONTEXT* pContext, U8 ** ppPayload,
                         U16* pLength, IP_COAP_CALLBACK_PARAM* pParam) {
    int Offset;
    (void)pContext;
    // Check the content-format if present.
    //
    if (IP_COAP_CheckContentFormat(pParam, IP_COAP_CT_TXT, 0) != IP_COAP_RETURN_OK) {
        return IP_COAP_RETURN_CT_FORMAT_ERROR;
    }
    //
    // Some init on the first block.
    //
    if (pParam->pBlock->Index == 0) {
        _InitData();
    }
    //
    // Copy the data block.
    //
    Offset = pParam->pBlock->Index * pParam->pBlock->Size;
    IP_COAP_MEMCPY(_Data + Offset, *ppPayload, *pLength);
    //
    // Perform some processing on the last block.
    //
    return IP_COAP_RETURN_OK;
}
```
if (IP_COAP_IsLastBlock(pParam, IP_COAP_CODE_REQ_GET) != 0) {
    _HandleGetEnd();
}
return IP_COAP_RETURN_OK;

The second example is a callback for a PUT/POST request.

static int _PUT_Handler(IP_COAP_CLIENT_CONTEXT * pContext, U8 ** ppPayload, U16* pLength, IP_COAP_CALLBACK_PARAM* pParam) {
    int Offset;
    U8* pBuf;
    U16 Length;
    U16 l;
    int r;
    (void)pContext;
    pBuf = *ppPayload;
    Length = *pLength;
    r = IP_COAP_RETURN_SEND_END; // By default, this is the last block.
    // Offset = pParam->pBlock->Index * pParam->pBlock->Size;
    if (Offset >= _PayloadLength) {
        _ErrorDetected = 1;
        return IP_COAP_RETURN_NO_PAYLOAD;
    }
    // Compute the remaining length of the payload not sent yet.
    // l = _PayloadLength - Offset;
    // If the remaining length of the payload is bigger than this
    // block size, reduce it to the block size.
    if (l > Length) {
        r = IP_COAP_RETURN_SEND_BLOCK; // More data to send in a next block.
        l = Length;
    }
   /IP_COAP_MEMCPY(pBuf, _Payload + Offset, l);
    pBuf += l;
    Length -= l;
    //
    *ppPayload = pBuf;
    *pLength = Length;

    return r;
}
35.8.10  Structure IP_COAP_API

Description
Contains the functions to perform the UDP receive and send as well as a function to get the current time in ms.

Prototype

```c
typedef struct {
    int (*pfReceive)(U8* pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO* pInfo, unsigned* pIsMulticast);
    int (*pfSend)(U8* pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO* pInfo);
    U32 (*pfGetTimeMs)();
} IP_COAP_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfReceive</td>
<td>Callback to receive UDP packets (see Callback pfReceive on page 1095)</td>
</tr>
<tr>
<td>pfSend</td>
<td>Callback to send UDP packets (see Callback pfSend on page 1095)</td>
</tr>
<tr>
<td>pfGetTimeMs</td>
<td>Callback to get the current time in milliseconds (see Callback pfGetTimeMs on page 1095).</td>
</tr>
</tbody>
</table>
### 35.8.11 Structure IP_COAP_CALLBACK_PARAM

**Description**

Argument of the payload callbacks describing connection parameters.

**Prototype**

```c
typedef struct {
    IP_COAP_BLOCK_INFO* pBlock;
    IP_COAP_CONN_INFO* pConnInfo;
    IP_COAP_HEADER_INFO* pHeader;
    IP_COAP_OPTIONS_INFO* pOptDesc;
} IP_COAP_CALLBACK_PARAM;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pBlock</code></td>
<td>Block information. See <a href="#">IP_COAP_BLOCK_INFO</a>.</td>
</tr>
<tr>
<td><code>pConnInfo</code></td>
<td>UDP connection information. See <a href="#">IP_COAP_CONN_INFO</a>.</td>
</tr>
<tr>
<td><code>pHeader</code></td>
<td>Parsed CoAP message header. See <a href="#">IP_COAP_HEADER_INFO</a>.</td>
</tr>
<tr>
<td><code>pOptDesc</code></td>
<td>CoAP message option description. See <a href="#">IP_COAP_OPTIONS_INFO</a>.</td>
</tr>
</tbody>
</table>

**Note**

Always check that the pointer is valid (not `NULL`) before accessing one of the different fields as some might not be set depending on the context.
35.8.12  Structure IP_COAP_OPTIONS_INFO

Description
CoAP options description.

Prototype

typedef struct {
    U32                      OptionPresentMask;   // Mask of IP_COAP_OPTMASK_xxx.
    U8*                      pHost;
    U8*                      pURI;
    U8*                      pQuery;
    U8*                      pETag;
    U8*                      pBlockLast;
    U8*                      pProxyURI;
    U8*                      pProxyScheme;
    IP_COAP_IF_MATCH_INFO*   pIfMatch;
    U32                      Observe;
    U32                      MaxAge;

</tbody>
</table>

**Additional information**

In the callbacks, it is recommended to access the options through the utility functions instead of directly accessing this structure as some options might have been reformatted.
35.8.13 Structure IP_COAP_IF_MATCH_INFO

**Description**
Utility structure to parametrize the If-Match option.

**Prototype**

```
struct {
    IP_COAP_IF_MATCH_INFO* pNext;
    U8* pETag;
    U8 ETagLength;
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pNext</td>
<td>Anchor of the linked list.</td>
</tr>
<tr>
<td>pETag</td>
<td>Pointer on the ETag value.</td>
</tr>
<tr>
<td>ETagLength</td>
<td>Length of the ETag value.</td>
</tr>
</tbody>
</table>

**Additional information**
This list is used to allow requesting more than one ETag in the If-Match option. When the ETagLength is 0 (pETag is NULL), the check is for all ETags, meaning it is an “existence” verification.
35.8.14 Structure IP_COAP_HEADER_INFO

Description
Parsed CoAP header.

Prototype

```c
typedef struct {
    U8  Type;
    U8  Code;
    U16 MessageId;
    U8  TokenLength;
    U8  aToken[8];
} IP_COAP_HEADER_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>CoAP message type (IP_COAP_TYPE_xxx).</td>
</tr>
<tr>
<td>Code</td>
<td>CoAP message code (IP_COAP_CODE_xxx).</td>
</tr>
<tr>
<td>MessageId</td>
<td>CoAP message id.</td>
</tr>
<tr>
<td>TokenLength</td>
<td>Length of <code>aToken</code>. Could be 0 if no token is present.</td>
</tr>
<tr>
<td>aToken</td>
<td>CoAP message token.</td>
</tr>
</tbody>
</table>
35.8.15 Structure IP_COAP_BLOCK_INFO

**Description**
Definition of the block used for Block1 and Block2 options.

**Prototype**

```c
typedef struct {
    U16 Index;
    U16 Size;
} IP_COAP_BLOCK_INFO;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>Index of the block. 0 is the first block.</td>
</tr>
<tr>
<td>Size</td>
<td>Size of the block.</td>
</tr>
</tbody>
</table>
35.8.16   Structure IP_COAP_CONN_INFO

Description
UDP connection definition.

Prototype

typedef struct {
    void* hSock;
    union {
        U8  IPAddrV6[16];
        U32 IPAddrV4;
    };
    U16   Port;
    U8    Family;
} IP_COAP_CONN_INFO;

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hSock</td>
<td>Socket information of the UDP connection. This field is not used by the CoAP processing, but only by the application callbacks pfReceive and pfSend. It could thus have any format adapted to the system.</td>
</tr>
<tr>
<td>IPAddrV6</td>
<td>IPv6 address.</td>
</tr>
<tr>
<td>IPAddrV4</td>
<td>IPv4 address</td>
</tr>
<tr>
<td>Port</td>
<td>UDP Port.</td>
</tr>
<tr>
<td>Family</td>
<td>Indication to use IPv4 (IP_COAP_IPV4) or IPv6 (IP_COAP_IPV6) address.</td>
</tr>
</tbody>
</table>
35.8.17 Callback pfReceive

Description
Callback used to receive UDP packets.

Prototype

```c
int (*pfReceive)(U8 * pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO * pInfo, unsigned * pIsMulticast);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBuffer</td>
<td>Start of the message buffer.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Length of the message buffer.</td>
</tr>
<tr>
<td>pInfo</td>
<td>UDP connection information.</td>
</tr>
<tr>
<td>pIsMulticast</td>
<td>Flag to set to indicate that the received message is a multicast/broadcast (1) or a unicast (0) message. If not known always set to 0.</td>
</tr>
</tbody>
</table>

35.8.18 Callback pfSend

Description
Callback used to send UDP packets.

Prototype

```c
int (*pfSend)(U8 * pBuffer, unsigned BufferSize, IP_COAP_CONN_INFO * pInfo);
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pBuffer</td>
<td>Start of the message buffer.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Length of the message.</td>
</tr>
<tr>
<td>pInfo</td>
<td>UDP connection information.</td>
</tr>
</tbody>
</table>

35.8.19 Callback pfGetTimeMs

Description
Callback used to get the current time in milliseconds.

Prototype

```c
U32 (*pfGetTimeMs)(void);
```
35.9  Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the CoAP client/server presented in the tables below have been measured on a Cortex-M4 system with the default configuration.

35.9.1  Server ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP CoAP server</td>
<td>approximately 9.2 kBytes</td>
</tr>
</tbody>
</table>

35.9.2  Client ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP CoAP client</td>
<td>approximately 6.5 kBytes</td>
</tr>
</tbody>
</table>

35.9.3  Server RAM usage.

All of the RAM used by the server is taken from task stacks or from the application configured buffers. The application needs to provide:

- Server main context: A context of type `IP_COAP_SERVER_CONTEXT` needs 132 bytes.
- Message buffer: Minimum size is 272 bytes (blocks of 16 bytes), maximum 1500.
- Server resources: A resource of type `IP_COAP_SERVER_DATA` needs 48 bytes plus all the string defining the resource (Uri-Path) if in memory (could be constant though).
- Client context: At least one client context of type `IP_COAP_SERVER_CLIENT_INFO` with a size of 144 bytes is needed. Depending on the load of the server, more clients may be required.
- Observer context: It is needed only if server provides observable data. One observer context of type `IP_COAP_OBSERVER` needs 56 bytes.

For a minimal server configuration without observable resources: 548 + Number of resources x 48 bytes.

35.9.4  Client RAM usage.

All of the RAM used by the client is taken from task stacks or from the application configured buffers. The application needs to provide:

- Client main context: A context of type `IP_COAP_CLIENT_CONTEXT` needs 184 bytes.
- Message buffer: Minimum size is 272 bytes (blocks of 16 bytes), maximum 1500.
- Observer context: It is needed only when registering to an observable data. One observer context of type `IP_COAP_CLIENT_OBS` needs 32 bytes.
The embOS/IP MQTT client is an optional extension to embOS/IP. The MQTT client can be used with embOS/IP or with a different TCP/IP stack. All functions that are required to add the MQTT client to your application are described in this chapter.
36.1 embOS/IP MQTT client

The embOS/IP MQTT client is an optional extension which can be seamlessly integrated into your TCP/IP application. It combines a maximum of performance with a small memory footprint.

The MQTT client implements the relevant parts of the following Standard.

<table>
<thead>
<tr>
<th>Standard#</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MQTT V 3.1.1</td>
<td>MQTT Version 3.1.1 Plus Errata 01</td>
</tr>
<tr>
<td></td>
<td>docs.oasis-open.org/mqtt/mqtt/v3.1.1/errata01/os/mqtt-v3.1.1-errata01-os-complete.pdf</td>
</tr>
</tbody>
</table>

The following table shows the contents of the embOS/IP MQTT client root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example application to run the MQTT client with embOS/IP.</td>
</tr>
<tr>
<td>.\Config\</td>
<td>Contains the MQTT client configuration file. Refer to MQTT client configuration on page 1104 for detailed information.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the MQTT client sources and header files, IP_MQTT_CLIENT.c and IP_MQTT_CLIENT.h.</td>
</tr>
<tr>
<td>.\Windows\IP\</td>
<td>Contains the source, the project files and executables to run the embOS/IP MQTT client on a Microsoft Windows host.</td>
</tr>
</tbody>
</table>
36.2 Feature list

- Full MQTT version 3.1 support.
- Publish/subscribe client included.
- Support for Quality of Service data delivery.
- Low memory footprint.
- Independent of the TCP/IP stack: any stack with sockets can be used.
- Example applications included.
- Project for executable on PC for Microsoft Visual Studio included.
36.3 Requirements

TCP/IP stack

The embOS/IP MQTT client requires a TCP/IP stack. It is optimized for embOS/IP, but any RFC-compliant TCP/IP stack can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API and an implementation which uses the socket API of embOS/IP.
36.4 MQTT backgrounds

MQTT is a very lightweight communication protocol originally designed for communication in M2M (Machine-To-Machine) contexts. It is easy to implement on the client side and has only a minimal packet overhead. This makes it ideal for the use with devices with limited resources.

It uses the publish/subscribe pattern, which is an alternative to the well known client/server model. In opposite to the client/server model, where a client directly communicates with an endpoint, the publish/subscribe pattern decouples the sender and receiver of a particular message. In the MQTT context the sending client is called publisher, the receiving client is called subscriber.

Publisher and subscriber do not know about the existence of one another. To enable the transport of a message, a third party is required. This third party is called a broker in the MQTT context. The broker distributes all incoming messages from the publishers to the subscribers, filtered on the topics the subscribers have assigned to.

MQTT uses topic-based filtering of messages. Publishers send topic related messages, subscribers receive messages if they have subscribed the topic.

To get messages a from a MQTT broker, a subscriber establishes a connection to the broker. The broker checks if a publisher has sent a message for the subscribed topic and if so, sends it to the subscriber. The advantage of this approach is that publisher and subscriber do not need to know each other and that they do not need to run at the same time. All they need to know is the IP address of the broker.
36.4.1 MQTT Quality of Service

embOS/IP MQTT client delivers application messages according to the chosen Quality of Service (QoS) level. The MQTT standard defines three qualities of service.

<table>
<thead>
<tr>
<th>Quality of service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QoS 0</td>
<td>QoS 0 is defined by the standard as “At most once”.</td>
</tr>
<tr>
<td>QoS 1</td>
<td>QoS 1 is defined by the standard as “At least once”.</td>
</tr>
<tr>
<td>QoS 2</td>
<td>QoS 2 is defined by the standard as “Exactly once”.</td>
</tr>
</tbody>
</table>

**QoS 0: At most once delivery**

Quality of service 0 means that the MQTT message is delivered according to the capabilities of the underlying network. The message arrives the receiver either once or not at all.

**QoS 1: At least once delivery**

Quality of service 1 means that the MQTT message arrives at the receiver at least once. Each QoS 1 PUBLISH packet contains a packet identifier and is acknowledged by a PUBACK packet from the receiver.

The PUBACK packet includes the packet identifier of the PUBLISH message, which should be acknowledged.
QoS 2: Exactly once delivery

Quality of service 2 means that the MQTT message will be arrive exactly once. Each QoS 2 PUBLISH packet contains a packet identifier. The receiver acknowledges receipt with a two-step acknowledgment process.

The receipt of a PUBLISH message with QoS 2 is replied with a PUBREC message. The PUBREC packet includes the packet identifier of the PUBLISH message, which should be acknowledged. With the receipt of the PUBREC message knows the sender of the PUBLISH packet, that the message has been received and replies with a PUBREL packet. After the receiver gets the PUBREL packet it can discard every stored state and sends PUBCOMP.
36.5 MQTT client configuration

The embOS/IP MQTT client can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

### Compile time configuration switches

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>IP_MQTT_CLIENT_WARN</td>
<td>--</td>
<td>Defines a function to output warnings. In debug configurations (<code>DEBUG = 1</code>) IP_MQTT_CLIENT_WARN maps to IP.Warnf_Application().</td>
</tr>
<tr>
<td>F</td>
<td>IP_MQTT_CLIENT_LOG</td>
<td>--</td>
<td>Defines a function to output logging messages. In debug configurations (<code>DEBUG = 1</code>) IP_MQTT_CLIENT_LOG maps to IP.Logf_Application().</td>
</tr>
</tbody>
</table>
## 36.6 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>MQTT client configuration functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Init()</td>
<td>Initializes an MQTT client.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_SetLastWill()</td>
<td>Sets the last will message of an MQTT client.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_SetUserPass()</td>
<td>Configures the username and password to be used to connect to a broker.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_SetKeepAlive()</td>
<td>Sets the KeepAlive period to be given to the broker when connecting to it.</td>
</tr>
<tr>
<td><strong>MQTT client operational functions</strong></td>
<td></td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Connect()</td>
<td>Connects a client to an MQTT broker.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Disconnect()</td>
<td>Disconnects a client from an MQTT broker.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Publish()</td>
<td>Publishes a message.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Subscribe()</td>
<td>Subscribes to one or more topics with a broker.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Unsubscribe()</td>
<td>Unsubscribes from one or more topics registered with a broker.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_WaitForNextMessage()</td>
<td>Waits for the next message ready to be received.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Recv()</td>
<td>Reads the payload of an MQTT message received.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Timer()</td>
<td>Timer function to handle maintenance tasks, like sending ping packets.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_Exec()</td>
<td>Maintenance and house keeping.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_ParsePublish()</td>
<td>Handles a PUBLISH message.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_IsClientConnected()</td>
<td>Checks if the client is connected to a broker.</td>
</tr>
</tbody>
</table>
36.6.1 IP_MQTT_CLIENT_Init()

**Description**
Initializes an MQTT client.

**Prototype**

```c
int IP_MQTT_CLIENT_Init(       IP_MQTT_CLIENT_CONTEXT       * pClient ,
                               char                          * pBuffer ,
                               U32                            BufferSize ,
                               const  IP_MQTT_CLIENT_TRANSPORT_API * pAPI ,
                               const  IP_MQTT_CLIENT_APP_API       * pAppAPI ,
                               const  char                          * sId );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to a memory block, which is used by the client to process MQTT messages.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Buffer size of pBuffer.</td>
</tr>
<tr>
<td>pAPI</td>
<td>Pointer to IP_MQTT_CLIENT_TRANSPORT_API structure.</td>
</tr>
<tr>
<td>pAppAPI</td>
<td>Pointer to IP_MQTT_CLIENT_APP_API structure.</td>
</tr>
<tr>
<td>sId</td>
<td>Pointer to a string which holds the client Id.</td>
</tr>
</tbody>
</table>

**Return value**

- \( \geq 0 \) O.K.
- \( = -1 \) Parameter error.

**Additional information**

The application needs to make sure that this function does not get called while IP_MQT-T_CLIENT_Timer() is active as it modifies internal lists that are accessed by it.
36.6.2   IP_MQTT_CLIENT_SetLastWill()

**Description**
Sets the last will message of an MQTT client.

**Prototype**

```c
int IP_MQTT_CLIENT_SetLastWill(IP_MQTT_CLIENT_CONTEXT * pClient,
                                IP_MQTT_CLIENT_MESSAGE * pLastWill);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>pLastWill</td>
<td>Pointer to IP_MQTT_CLIENT_MESSAGE structure which holds the message to set as last will on the broker.</td>
</tr>
</tbody>
</table>

**Return value**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>O.K., last will set.</td>
</tr>
<tr>
<td>-1</td>
<td>Error, could not set last will (currently connected ?).</td>
</tr>
</tbody>
</table>

**Additional information**

This function needs to be called before connect as the last will parameter is given to the broker during connect. The `pLastWill` message needs to remain valid until `IP_MQTT_CLIENT_Connect()` is done and for every further calls to `IP_MQTT_CLIENT_Connect()`.
36.6.3 IP_MQTT_CLIENT_SetUserPass()

Description
Configures the username and password to be used to connect to a broker.

Prototype

```c
int IP_MQTT_CLIENT_SetUserPass(       IP_MQTT_CLIENT_CONTEXT * pClient,
                                   const char                    * sUser,
                                   const char                    * sPass);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>sUser</td>
<td>Username to use.</td>
</tr>
<tr>
<td>sPass</td>
<td>Password to use.</td>
</tr>
</tbody>
</table>

Return value

- 0   O.K.
- -1  Error, could not set user/pass (currently connected?).

Additional information

This function is optional. Username and password are only required if the broker needs them for authentication.

This function needs to be called before connect as the username and password is given to the broker during connect. `sUser` and `sPass` need to remain valid until `IP_MQTT_CLIENT_Connect()` is done and for every further calls to `IP_MQTT_CLIENT_Connect()`. 
36.6.4 IP_MQTT_CLIENT_SetKeepAlive()

**Description**
Sets the KeepAlive period to be given to the broker when connecting to it.

**Prototype**

```c
int IP_MQTT_CLIENT_SetKeepAlive ( IP_MQTT_CLIENT_CONTEXT * pClient, U16 KeepAlive);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>KeepAlive</td>
<td>KeepAlive period [s] told to the broker.</td>
</tr>
</tbody>
</table>

**Return value**

- 0 O.K.
- -1 Error, could not set timeout (currently connected ?).

**Additional information**

The KeepAlive is a time interval measured in seconds. Expressed as a 16-bit word, it is the maximum time interval that is permitted to elapse between the point at which the client finishes transmitting one control packet and the point it starts sending the next.

If the KeepAlive value is non-zero and the broker does not receive a control packet from the client within one and a half times the KeepAlive time period, it MUST disconnect the network connection to the client as if the network had failed.

This function is optional. By default the KeepAlive value is set to zero, since TCP layer can ensure the stability by using TCP KEEPALIVE packets. If you configure a non-zero value you need to call the MQTT timer function on a regular basis. For further information please refer to IP_MQTT_CLIENT_Timer().
36.6.5 IP_MQTT_CLIENT_Connect()

Description
Connects a client to an MQTT broker. Establishes a TCP connection and handles the MQTT connect.

Prototype

```c
int IP_MQTT_CLIENT_Connect(       IP_MQTT_CLIENT_CONTEXT * pClient,
                                 const char                    * sAddr,
                                 U16                      Port,
                                 U8                       CleanSession);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>sAddr</td>
<td>String with address of the broker.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port of the broker.</td>
</tr>
<tr>
<td>CleanSession</td>
<td>• 0: Reuse old session data to continue.</td>
</tr>
<tr>
<td></td>
<td>• 1: Start with a clean session.</td>
</tr>
</tbody>
</table>

Return value

0    O.K., client connected.
-1   Error.
36.6.6  IP_MQTT_CLIENT_Disconnect()

Description
Disconnects a client from an MQTT broker.

Prototype

```c
int IP_MQTT_CLIENT_Disconnect(IP_MQTT_CLIENT_CONTEXT * pClient);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
</tbody>
</table>

Return value

- `> 0`  O.K., client disconnected.
- `= -1` Error, already disconnected ?

Additional information

Disconnecting means that the MQTT client, sends a MQTT disconnect packet and closes thereafter the transport layer connection.
CHAPTER 36

API functions

### 36.6.7 IP_MQTT_CLIENT_Publish()

**Description**

Publishes a message.

**Prototype**

```c
int IP_MQTT_CLIENT_Publish ( IP_MQTT_CLIENT_CONTEXT * pClient,
                               IP_MQTT_CLIENT_MESSAGE * pPublish );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>pPublish</td>
<td>Pointer to an IP_MQTT_CLIENT_MESSAGE structure.</td>
</tr>
</tbody>
</table>

**Return value**

- > 0 Keep message.
- = 0 O.K., PUBLISH message sent.
- = -1 Error, could not send PUBLISH message.
36.6.8 IP_MQTT_CLIENT_Subscribe()

Description
Subscribes to one or more topics with a broker.

Prototype

```c
int IP_MQTT_CLIENT_Subscribe(IP_MQTT_CLIENT_CONTEXT   *  pClient,
                              IP_MQTT_CLIENT_SUBSCRIBE * pSubscribe);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>pSubscribe</td>
<td>Pointer to IP_MQTT_CLIENT_SUBSCRIBE structure.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>O.K.</td>
</tr>
<tr>
<td>= -1</td>
<td>Error, could not subscribe.</td>
</tr>
</tbody>
</table>
36.6.9  IP_MQTT_CLIENT_Unsubscribe()

Description
Unsubscribes from one or more topics registered with a broker.

Prototype

```c
int IP_MQTT_CLIENT_Unsubscribe ( IP_MQTT_CLIENT_CONTEXT   *  pClient ,
                                IP_MQTT_CLIENT_SUBSCRIBE *  pUnsubscribe );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
<tr>
<td>pUnsubscribe</td>
<td>Pointer to IP_MQTT_CLIENT_SUBSCRIBE structure.</td>
</tr>
</tbody>
</table>

Return value

0  O.K.
-1  Error, could not unsubscribe.
36.6.10  IP_MQTT_CLIENT_WaitForNextMessage()

Description
Waits for the next message ready to be received.

Prototype

```c
int IP_MQTT_CLIENT_WaitForNextMessage(IP_MQTT_CLIENT_CONTEXT * pClient,
                                       U32 * pType,
                                       U32 * pNumBytesRecv,
                                       char * pBuffer,
                                       U32 BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to an MQTT client structure.</td>
</tr>
<tr>
<td>pType</td>
<td>Pointer to a U32 to store the packet type.</td>
</tr>
<tr>
<td>pNumBytesRecv</td>
<td>Pointer to a U32 to store how much data can be received using IP_MQTT_CLIENT_Recv().</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to the buffer to store the topic of the received message. Can be NULL.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of the buffer at pBuffer.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>Length of the message topic received.</td>
</tr>
<tr>
<td>= 0</td>
<td>Connection has been gracefully closed by the broker.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>
36.6.11  IP_MQTT_CLIENT_Recv()

Description
Reads the payload of an MQTT message received.

Prototype

```c
int IP_MQTT_CLIENT_Recv ( IP_MQTT_CLIENT_CONTEXT * pClient,
                            char                    * pBuffer,
                            U32                      BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to an MQTT client structure.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to buffer to store data from message.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of buffer at pBuffer.</td>
</tr>
</tbody>
</table>

Return value

- > 0  O.K., number of bytes received.
- = 0  Connection has been gracefully closed by the broker.
- < 0  Error.

Additional information

Can be called multiple times with a small buffer to read the payload in chunks.
36.6.12  IP_MQTT_CLIENT_Timer()

Description
Timer function to handle maintenance tasks, like sending ping packets.

Prototype

```c
void IP_MQTT_CLIENT_Timer(void);
```

Additional information
This function might be required for background tasks. Typically the connection stability is ensured by the underlying TCP protocol and therefore does not need further assistance like pings on another layer. embOS/IP by default enables KEEPALIVES for TCP sockets and this is advised to be used with sockets on any other TCP/IP stack as well.

In case IP_MQTT_CLIENT_SetKeepAlive() is used, the timer has to be called on a regular basis to satisfy your own configuration that has been set using IP_MQTT_CLIENT_SetKeepAlive().
36.6.13  IP_MQTT_CLIENT_Exec()

Description
Maintenance and house keeping.

Prototype

```c
int IP_MQTT_CLIENT_Exec ( IP_MQTT_CLIENT_CONTEXT * pClient );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to IP_MQTT_CLIENT_CONTEXT structure.</td>
</tr>
</tbody>
</table>

Return value

- > 0  O.K.
- = 0  Connection gracefully closed by peer.
- < 0  Error.

Additional information

This function is only required, if the MQTT client will be called from several tasks. Please refer to the sample application IP_MQTT_CLIENT_PublisherSubscriber_2Tasks.c for detailed information.
36.6.14  IP_MQTT_CLIENT_ParsePublish()

Description
Handles a PUBLISH message.

Prototype

```c
int  IP_MQTT_CLIENT_ParsePublish ( IP_MQTT_CLIENT_MESSAGE  *  pPublish,
                                                   char                     *  pBuffer,
                                                   int                        NumBytes,
                                                   char                    **  ppTopic,
                                                   int                      *  pNumBytesTopic,
                                                   char                    **  ppPayload,
                                                   int                      *  pNumBytesPayload);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pPublish</td>
<td>Pointer to a MQTT_PUBLISH_MESSAGE structure.</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Pointer to the start of the publish message.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Number of bytes stored in the buffer.</td>
</tr>
<tr>
<td>ppTopic</td>
<td>Pointer to the topic of the publish message. Can be NULL.</td>
</tr>
<tr>
<td>pNumBytesTopic</td>
<td>Pointer to an int store the length of the topic. Can be NULL.</td>
</tr>
<tr>
<td>ppPayload</td>
<td>Pointer to the payload of the publish message.</td>
</tr>
<tr>
<td>pNumBytesPayload</td>
<td>Pointer to an int to store the length of the payload.</td>
</tr>
</tbody>
</table>

Return value

= 0  O.K.
< 0  Error.

Additional information

This function is only required, if the MQTT client will be called from several tasks. Please refer to the sample application IP_MQTT_CLIENT_PublisherSubscriber_2Tasks.c for detailed information.
36.6.15  IP_MQTT_CLIENT_IsClientConnected()

Description
Checks if the client is connected to a broker.

Prototype

```c
int IP_MQTT_CLIENT_IsClientConnected(const IP_MQTT_CLIENT_CONTEXT * pClient);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pClient</td>
<td>Pointer to an MQTT client structure.</td>
</tr>
</tbody>
</table>

Return value

- > 0  Connected
- = 0  Not connected

Additional information

This function is only required, if the MQTT client will be called from several tasks. Please refer to the sample application IP_MQTT_CLIENT_PublisherSubscriber_2Tasks.c for detailed information.
## 36.7 Data structures

<table>
<thead>
<tr>
<th>Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MQTT_CLIENT_TRANSPORT_API</td>
<td>Transport API function pointer.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_APP_API</td>
<td>Application related function pointer.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_MESSAGE</td>
<td>Message maintenance structure.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_TOPIC_FILTER</td>
<td>Topic filter structure.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_SUBSCRIBE</td>
<td>Subscribe structure.</td>
</tr>
</tbody>
</table>
36.7.1  Structure IP_MQTT_CLIENT_TRANSPORT_API

Description
Structure with pointers to the required socket interface functions.

Prototype

```c
typedef struct IP_MQTT_CLIENT_TRANSPORT_API {
    void* (*pfConnect) (char* SrvAddr, unsigned SrvPort);
    void (*pfDisconnect)(void* pSocket);
    int (*pfReceive)(void* pSocket, char* pData, int Len);
    int (*pfSend)(void* pSocket, const char* pData, int Len);
} IP_MQTT_CLIENT_TRANSPORT_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfConnect</td>
<td>Pointer to the connect function (for example, <code>connect()</code>).</td>
</tr>
<tr>
<td>pfDisconnect</td>
<td>Pointer to the disconnect function (for example, <code>closesocket()</code>).</td>
</tr>
<tr>
<td>pfSend</td>
<td>Pointer to a callback function (for example, <code>send()</code>).</td>
</tr>
<tr>
<td>pfRecv</td>
<td>Pointer to a callback function (for example, <code>recv()</code>).</td>
</tr>
</tbody>
</table>
36.7.2  Structure IP_MQTT_CLIENT_APP_API

Description
Structure with pointers to the required functions.

Prototype

```c
typedef struct IP_MQTT_CLIENT_APP_API {
    U16   (*pfGenRandom)            (  void  );
    void* (*pfAlloc)                (  U32   NumBytesReq );
    void (*pfFree)                 (  void* p );
    void (*pfLock)                 (  void  );
    void (*pfUnlock)               (  void );
    int (*pfRecvMessage)          (  void* pMQTTClient,
                       void* pPublish,
                       int NumBytesRem );
    // Get the subscribed message
    int (*pfOnMessageConfirm)     (  void* pMQTTClient,
                       U8 Type,
                       U16 PacketId );
    // Inform the application that a message has been processed
    int (*pfHandleError)          (  void* pMQTTClient );
    // Inform the application that the publishing of a message failed.
}  IP_MQTT_CLIENT_APP_API;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfGenRandom</td>
<td>Pointer to a function which returns a random unsigned short value. The random value is used for the packet ID of MQTT packets.</td>
</tr>
<tr>
<td>pfAlloc</td>
<td>Pointer to the Alloc() function. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfFree</td>
<td>Pointer to the Free() function. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfLock</td>
<td>Pointer to a function which acquires a lock to ensure MQTT API is thread safe. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfUnlock</td>
<td>Pointer to a function which releases a previously acquired lock for thread safety MQTT API. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfRecvMessage</td>
<td>Pointer to a function which returns a random unsigned short value. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfOnMessageConfirm</td>
<td>Pointer to a function which returns a random unsigned short value. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
<tr>
<td>pfHandleError</td>
<td>Pointer to a function which returns a random unsigned short value. This function is only required, if you plan to call the MQTT client API from several tasks (e.g. MQTT client acts as subscriber and publisher.)</td>
</tr>
</tbody>
</table>
36.7.3 Structure IP_MQTT_CLIENT_MESSAGE

Description
Message maintenance structure.

Prototype

```c
typedef struct IP_MQTT_CLIENT_MESSAGE {
    IP_MQTT_DLIST_ITEM Link;
    char* sTopic;
    char* pData;
    U32 DataLen;
    U16 PacketId;
    U8 QoS;
    U8 Retain;
    U8 Duplicate;
} IP_MQTT_CLIENT_MESSAGE;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sTopic</td>
<td>Pointer to the topic string.</td>
</tr>
<tr>
<td>pData</td>
<td>Pointer to the payload which should be published.</td>
</tr>
<tr>
<td>DataLen</td>
<td>Number of payload bytes.</td>
</tr>
<tr>
<td>PacketId</td>
<td>Packet ID. (Will be filled by the MQTT client module)</td>
</tr>
<tr>
<td>QoS</td>
<td>QoS flag.</td>
</tr>
<tr>
<td>Retain</td>
<td>Retain flag.</td>
</tr>
<tr>
<td>Duplicate</td>
<td>Duplicate flag. (Will be filled by the MQTT client module)</td>
</tr>
</tbody>
</table>

Valid values for parameter QoS

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS0</td>
<td>Quality of service level 0. “At most once”.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS1</td>
<td>Quality of service level 1. “At least once”.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS2</td>
<td>Quality of service level 2. “Exactly once”.</td>
</tr>
</tbody>
</table>

Additional information
For detailed information about the different quality of service levels, refer to MQTT Quality of service on page 1102.
36.7.4 Structure IP_MQTT_CLIENT_TOPIC_FILTER

Description
Structure used to subscribe to a particular topic.

Prototype

```c
typedef struct IP_MQTT_CLIENT_TOPIC_FILTER {
    char * sTopicFilter;
    U16   Length;
    U8    QoS;
} IP_MQTT_CLIENT_TOPIC_FILTER;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sTopicFilter</td>
<td>Pointer to the topic filter string (zero-terminated).</td>
</tr>
<tr>
<td>Length</td>
<td>Length of the topic.</td>
</tr>
<tr>
<td>QoS</td>
<td>Quality of service flag.</td>
</tr>
</tbody>
</table>

Valid values for parameter QoS

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS0</td>
<td>Quality of service level 0.</td>
</tr>
<tr>
<td></td>
<td>“At most once”.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS1</td>
<td>Quality of service level 1.</td>
</tr>
<tr>
<td></td>
<td>“At least once”.</td>
</tr>
<tr>
<td>IP_MQTT_CLIENT_FLAGS_PUBLISH_QOS2</td>
<td>Quality of service level 2.</td>
</tr>
<tr>
<td></td>
<td>“Exactly once”.</td>
</tr>
</tbody>
</table>

Additional information
For detailed information about the different quality of service levels, refer to MQTT Quality of service on page 1102.
### 36.7.5 Structure IP_MQTT_CLIENT_SUBSCRIBE

**Description**

Structure used by the `IP_MQTT_CLIENT_Subscribe()` function to subscribe to many topics at once. The topics are described in an array of `IP_MQTT_CLIENT_TOPIC_FILTER`.

**Prototype**

```c
typedef struct IP_MQTT_CLIENT_SUBSCRIBE {
    IP_MQTT_DLIST_ITEM           Link;
    IP_MQTT_CLIENT_TOPIC_FILTER*  pTopicFilter;
    int                           TopicCnt;
    U16                          PacketId;
    U8                           ReturnCode;
}  IP_MQTT_CLIENT_SUBSCRIBE;
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pTopicFilter</td>
<td>Pointer to the first topic filter structure.</td>
</tr>
<tr>
<td>TopicCnt</td>
<td>Number of added topics.</td>
</tr>
<tr>
<td>PacketId</td>
<td>Packet ID. (Will be filled by the MQTT client module)</td>
</tr>
<tr>
<td>ReturnCode</td>
<td>Return code. (Will be filled by the MQTT client module)</td>
</tr>
</tbody>
</table>
36.8 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the MQTT client presented in the tables below have been measured on a Cortex-M4 system. Details about the further configuration can be found in the sections of the specific example.

36.8.1 Resource usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio, size optimized.

36.8.1.1 ROM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP MQTT client</td>
<td>approximately 2.5 kBytes</td>
</tr>
</tbody>
</table>

36.8.1.2 RAM usage

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP MQTT client context w/o task stack</td>
<td>approximately 60 Bytes</td>
</tr>
</tbody>
</table>
Chapter 37
WebSocket (Add-on)

The embOS/IP WebSocket IoT (Internet of Things) protocol is an optional extension to embOS/IP. The WebSocket add-on can be used with embOS/IP or with a different TCP/IP stack that uses a socket API. All functions that are required to add WebSocket support to your application are described in this chapter.
37.1 embOS/IP WebSocket support

The embOS/IP WebSocket add-on is an optional extension which adds WebSocket functionality to your application. It has been implemented with the limitations of an embedded system in mind while still providing a flexible but powerful API paired with a small memory footprint. The RAM usage has been kept to a minimum by smart handling of the protocols characteristics.

The WebSocket add-on implements the relevant parts of the following Request For Comments (RFC).

<table>
<thead>
<tr>
<th>RFC#</th>
<th>Description</th>
</tr>
</thead>
</table>

The following table shows the contents of the embOS/IP WebSocket package root directory:

<table>
<thead>
<tr>
<th>Directory</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>.\Application\</td>
<td>Contains the example applications to run a WebSocket printf() server/client with embOS/IP.</td>
</tr>
<tr>
<td>.\IP\</td>
<td>Contains the WebSocket sources IP_WEBSOCKET.c and IP_WEBSOCKET.h.</td>
</tr>
<tr>
<td>.\Windows\IP\WebSocket_printf_Server\</td>
<td>Contains the source, the project files and an executable to run the embOS/IP WebSocket add-on (server side) on a Microsoft Windows host. Refer to Using the WebSocket samples on page 1139 for detailed information.</td>
</tr>
<tr>
<td>.\Windows\IP\WebSocket_printf_Client\</td>
<td>Contains the source, the project files and an executable to run the embOS/IP WebSocket add-on (client side) on a Microsoft Windows host. Refer to Using the WebSocket samples on page 1139 for detailed information.</td>
</tr>
</tbody>
</table>
37.2 Feature list

- Converts a synchronous HTTP connection into an asynchronous data connection.
- Can traverse firewalls using the well known HTTP port.
- Can be used with or without web server.
- Seamless integration with the embOS/IP web server add-on.
- Low memory footprint.
- Optimized API for embedded systems.
- Independent of the TCP/IP stack: any stack with sockets can be used.
- Project for executable on PC for Microsoft Visual Studio included.
37.3 Requirements

TCP/IP stack

The embOS/IP WebSocket add-on requires a TCP/IP stack. It is optimized for embOS/IP, but any RFC-compliant TCP/IP stack that has a socket API can be used. The shipment includes a Win32 simulation, which uses the standard Winsock API as well as an implementation which uses the socket API of embOS/IP.
37.4 Backgrounds

The WebSocket protocol is an IoT (Internet of Things) protocol that allows to upgrade a regular synchronous HTTP connection into an asynchronous bidirectional data tunnel. It allows to establish a regular HTTP connection with a webserver, checking if both sides, client and server, understand the WebSocket protocol depending on the answer sent back by the webserver.

The non intrusive test for checking the WebSocket protocol being supported is compatible with the HTTP/1.1 standard and will return a page with an error code in worst case if the protocol is not supported by the webserver. The webserver service for serving regular pages remains fully operational while coexisting with the WebSocket protocol.

The WebSocket protocol is using the TCP/IP protocol for data, using the HTTP/1.1 protocol only to initially establish a WebSocket connection.

An advantage of the WebSocket protocol is that it establishes a connection through the HTTP protocol. This allows an easier handling in terms of firewalls as typically the standard port TCP 80 is allowed for outgoing connections, allowing WebSocket clients to work without problems. For a WebSocket server, offering webpages and WebSocket tunneled protocols only a single port is required to be opened in the firewall or allowed to be forwarded by a router from the Internet to your local network.
37.4.1 Establishing a WebSocket connection

Before application data can be transferred, a connection handshake needs to be done. The handshake is done sending a regular HTTP/1.1 protocol request to a webserver that contains WebSocket specific extension fields in the HTTP header as well as a list of WebSocket subprotocols that the client is able to use.

```
GET /printf HTTP/1.1
Host: 192.168.11.158
Connection: Upgrade
Upgrade: websocket
Sec-WebSocket-Version: 13
Sec-WebSocket-Key: ew+1nlIjRf4c+zVtzqI22g==
Sec-WebSocket-Protocol: debug
```

The sample above shows the minimum HTTP header that is sent by a WebSocket client to a webserver to establish a WebSocket connection. The following header fields are used in the request:

<table>
<thead>
<tr>
<th>Header field</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Request</strong></td>
<td>The very first line expected contains the METHOD used for access (for WebSocket this is always “GET”), the resource that is accessed (in this sample “/printf”) and the HTTP protocol version used (“HTTP/1.1”).</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>The host name to access. For webservers that host multiple domains the “Host:” field specifies the domain to use.</td>
</tr>
<tr>
<td><strong>Connection</strong></td>
<td>Extra actions requested for the HTTP connection. In the sample above a connection “Upgrade” is requested. The type of upgrade is then specified by the “Upgrade:” field.</td>
</tr>
<tr>
<td><strong>Upgrade</strong></td>
<td>The type of connection upgrade requested. In the sample above the connection shall be upgraded to the “websocket” protocol.</td>
</tr>
<tr>
<td><strong>Sec-WebSocket-Version</strong></td>
<td>The highest WebSocket protocol version supported by the client. 13 is the first final WebSocket protocol version.</td>
</tr>
<tr>
<td><strong>Sec-WebSocket-Key</strong></td>
<td>Key value that is used to verify that the webserver is really understanding the WebSocket protocol.</td>
</tr>
<tr>
<td><strong>Sec-WebSocket-Protocol</strong></td>
<td>WebSocket subprotocols supported by the client. In the sample above we use the sample subprotocol “debug”.</td>
</tr>
</tbody>
</table>
37.4.2 Accepting a WebSocket connection

To accept a WebSocket connection the webserver needs to send back a HTTP header to the client confirming the protocol upgrade. In case the webserver is not aware of the WebSocket protocol or the resource requested is not available, the webserver can send back its regular HTTP error code and content.

The client expects a HTTP 101 “Switching Protocols” response in case the webserver supports the WebSocket protocol. Any other HTTP code returned by the webserver means that the WebSocket protocol, the resource or the selected subprotocol is not supported.

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Protocol: debug
Sec-WebSocket-Accept: fwgzotwyvIXhoZ/o77F3O8wc8Pc=
```

The sample above is the minimum HTTP response header sent back by a webserver to accept the WebSocket connection upgrade. The following header fields are different in the response:

<table>
<thead>
<tr>
<th>Header field</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Response</td>
<td>The response code “101” confirms that a protocol switch has been done. The explanation “Switching Protocols” is typically added but should only serve as additional text that might differ.</td>
</tr>
<tr>
<td>Sec-WebSocket-Protocol</td>
<td>WebSocket subprotocols supported by the client. In the sample above we use the sample subprotocol “debug”.</td>
</tr>
<tr>
<td>Sec-WebSocket-Accept</td>
<td>This value is calculated based on the value of the <code>Sec-WebSocket-Key</code> field from the request and is an additional indicator that the WebSocket protocol is fully understood by the webserver.</td>
</tr>
</tbody>
</table>
37.4.3 Closing a WebSocket connection

Closing a WebSocket connection is basically very easy. As the underlying protocol is TCP, a close of the TCP socket means closing the WebSocket connection as well. While this will always work it is suggested to first close the WebSocket connection itself before closing the TCP socket. This allows sending the other side a reason why the connection is closed. This can be done using the function `IP_WEBSOCKET_Close()`.

37.4.4 WebSocket data framing

The WebSocket protocol combines the following properties of TCP and UDP:

TCP properties
- Lost data is retransmitted.
- Data is received in the correct order.
- The connection status can be checked by using TCP KEEPALIVES.

UDP properties
- Data can be sent in small frames (while being part of a larger message).
- The length of the frame is known (the complete message length is not).
- Control frames (UDP: other data) can be sent between data frames.
Principle of operation

Application data sent using the WebSocket protocol can be described as UDP like framing of data within a TCP data stream. While this might sound complex at first, the protocol itself is not.

The main purpose of the WebSocket protocol is to allow a device with limited resources sending one big block of data in chunks (called a frames in the WebSocket protocol) whenever data is ready/generated instead of collecting the data before sending. At the same time control commands should be able to be processed anytime between frames. At the same time the TCP protocol ensures that data is not lost and frames will be sent and received in the correct order.

The WebSocket protocol achieves these goals by sending all data in frames that have a header upfront. The encapsulation of the protocol is shown below:

The WebSocket header size is between 2 and 14 bytes and contains information about the position of the frame in context to the complete data to send (first, one of the middle, last frame of a message) as well as the length of the application data in this single frame.
### 37.4.5 WebSocket frame types

WebSocket frames contain a frame type in their header. The following types are available for WebSocket protocol version 13:

<table>
<thead>
<tr>
<th>Frame type</th>
<th>ID</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_CONTINUE</td>
<td>0x00</td>
<td>The data in this frame is continuation of the last frame with an ID other than 0x00.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_TEXT</td>
<td>0x01</td>
<td>Used for sending an unterminated textual string.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_BINARY</td>
<td>0x02</td>
<td>Used to send any type of data.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_CLOSE</td>
<td>0x08</td>
<td>Used to close the message with a close code and an optional message.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_PING</td>
<td>0x09</td>
<td>PING request.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_FRAME_TYPE_PONG</td>
<td>0x0A</td>
<td>PING response.</td>
</tr>
</tbody>
</table>

Typically there are only two frame types that are relevant for the application. These are `IP_WEBSOCKET_FRAME_TYPE_TEXT` and `IP_WEBSOCKET_FRAME_TYPE_BINARY`. They specify the type of a received message. However if the application uses a custom protocol and does not need to distinguish between text and binary data the frame type `IP_WEBSOCKET_FRAME_TYPE_BINARY` can always be used.

All other frame types are control frame types. Control frames can be sent in between message frames to allow an immediate processing instead of having to wait for all frames of a message to be transferred. Controls frames are handled by the WebSocket protocol in the background. The only exception to this is a frame of the type `IP_WEBSOCKET_FRAME_TYPE_CLOSE` as this allows the application to close the WebSocket connection gracefully sending a close code itself and an optional message.
37.5 Using the WebSockets samples

Ready to use examples for Microsoft Windows and embOS/IP are supplied. If you use another TCP/IP stack, the samples have to be adapted.

The supplied sample application IP_WEBSOCKET_printf_Server.c and GUI_VNC_XStartServer.c show different approaches for implementing the WebSocket protocol. While both accept a WebSocket connection their implementation and handling of the connection is completely different.

37.5.1 IP_WEBSOCKET_printf_Server.c

This sample accepts a WebSocket connection and awaits messages of the frame type IP_WEBSOCKET_FRAME_TYPE_TEXT. It tries to copy received text messages into a local buffer to string terminate them and then outputs them to the standard output using printf().

The WebSocket connection handshake is done without a web server by parsing the request HTTP header for the "Sec-WebSocket-Key:" header field value and sending back its counterpart in a HTTP response.

The message handling of the established WebSocket connection is handled by the same task that accepts the connection, blocking it for accepting further WebSocket connections while one connection is ongoing.

Testing the sample

To test the sample, a WebSocket client is necessary. One of these clients is the "Dark WebSocket terminal" (DWST) that is available as extension for the Chrome browser.

Connect

To connect to the WebSocket printf() server enter the following command:

```
/connect ws://<IP addr. of server>/printf debug
```
This will open a connection to the server using the resource “/printf” and suggesting the subprotocol “debug”.

**Send a text that the target will printf()**

Once the WebSocket connection is established, text can be send to the server that will the be printf() processed. A “Hello World!” can be send using the following command:

```
/send Hello World!
```

Some characters need to be escaped using a backslash. In the above sample the whitespace needs to be written as " " (backslash followed by a space) as the whitespace is a separator character in case commands can have parameters.

**Disconnect**

To disconnect from the server the following line can be executed:

```
/disconnect
```

This will send a frame of type `IP_WEBSOCKET_FRAME_TYPE_CLOSE` to the server. The server should then simply close the TCP connection. However in a good manner the server might send its own frame of type `IP_WEBSOCKET_FRAME_TYPE_CLOSE` back for a graceful close of the WebSocket connection before closing the TCP connection.

**Sample output**

The following is a screenshot of the commands described above:

The output of a terminal on the server side should show the following lines:

```
WebSocket client connected.
Client: Hello World!
WebSocket client disconnected.
```
37.5.2 GUI_VNC_X_StartServer.c

This sample consists of a part of the emWin VNC Server setup. The file GUI_VNC_X_StartServer.c contains the TCP/IP abstraction between emWin and a TCP/IP stack. It can be found in the folder "\Shared\GUI\Sample". The sample adds a resource hook to the web server that allows using the emWin VNC server with the noVNC client, written entirely in HTML5.

The latest version of the noVNC client can be downloaded from the following location: https://github.com/kanaka/noVNC/releases

noVNC works best when used with the Chrome browser. Inconsistent HTML5 implementations in different browsers result in problems running noVNC.

Precautions

The following precautions need to be met for connecting with noVNC:

- The embOS/IP web server add-on has been added to a target running the emWin VNC server.
- The define GUI_VNC_SUPPORT_WEBSOCKET_SERVER has been set to “1” in the project settings or the file itself to enable the WebSocket implementation.
- The WebSocket resource hooked into the web server is configured for the path “/websockify” and the subprotocol “binary”. Both values are the defaults for noVNC.

By registering the WebSocket resource with the web server using IP_WEBS_WEBSOCKET_AddHook(), the web server remains able to serve its regular webpages while at the same time allowing to accept WebSocket connections under the registered resource path “/websockify” and executing the WebSocket handshake with a client.

An accepted WebSocket connection can be handled by the web server in two ways:

- Executing the WebSocket message handling from the same task context, blocking the web server resource (web server child task) from being reused until the WebSocket connection is closed.
- Dispatching the connection handle to another context, freeing the web server resource for another request.

For this sample the latter is used, dispatching the connection handle used by the web server to the VNC server task for further processing. Dispatching another WebSocket connection is disabled and further WebSocket connections will be discarded until the noVNC client gets disconnected.
Testing the sample

To test the noVNC client with the emWin VNC server with WebSocket support please make sure the precautions described above are met. Start the noVNC client by opening the file “vnc.html” from the noVNC package in your browser. The only thing to do is to enter the IP address or host name of your WebSocket/VNC server and the port the web server listens on as shown in the screenshot below:

![Screenshot of noVNC client](image)

By pressing the “Connect” button noVNC establishes a WebSocket connection with the web server. The established connection is then dispatched to the VNC server task as described before.

While it is possible to connect to the VNC server with a regular VNC client and noVNC, it is not possible at the same time due to the limitations of the sample.
37.5.3 Using the Windows sample

If you have MS Visual C++ 6.00 or any later version available, you will be able to work with a Windows sample project using the embOS/IP WebSocket add-on. If you do not have the Microsoft compiler, a precompiled executable of the “WebSockets printf Server” is also supplied.

Building the sample program

Open the workspace WebSocket_printf.dsw with MS Visual Studio (for example, double-clicking it). There is no further configuration necessary. You should be able to build the application without any error or warning message.

Testing the sample program

The server uses the IP address of the host PC on which it runs. Unlike the embOS/IP sample, the Windows sample does not use port 80 but instead uses port 8181. This is due to port 80 being used by Windows by default from Windows 8 onwards.

The sample can be tested the same way as its embOS/IP counterpart using a WebSocket client like Dark WebSocket Terminal (DWST). The sample shows some tests commands as online help during startup as shown below.

![Sample output](image-url)
37.6 Configuration

The embOS/IP WebSocket add-on can be used without changing any of the compile time flags. All compile time configuration flags are preconfigured with valid values, which match the requirements of most applications.

The following types of configuration macros exist:

**Binary switches "B"**

Switches can have a value of either 0 or 1, for deactivated and activated respectively. Actually, anything other than 0 works, but 1 makes it easier to read a configuration file. These switches can enable or disable a certain functionality or behavior. Switches are the simplest form of configuration macros.

**Numerical values "N"**

Numerical values are used somewhere in the source code in place of a numerical constant. A typical example is the configuration of the sector size of a storage medium.

**Alias "A"**

A macro which operates like a simple text substitute. An example would be the define `U8`, which the preprocessor would replace with `unsigned char`.

**Function replacements "F"**

Macros can basically be treated like regular functions although certain limitations apply, as a macro is still put into the source code as simple text replacement. Function replacements are mainly used to add specific functionality to a module which is highly hardware-dependent. This type of macro is always declared using brackets (and optional parameters).

**Compile time configuration switches**

<table>
<thead>
<tr>
<th>Type</th>
<th>Symbolic name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>IP_WEBSOCKET_MAX_DATA_SIZE</td>
<td>16384</td>
<td>Maximum amount of bytes that can be transferred in one WebSocket frame. The payload length of a WebSocket frame is an U64 value, however underlying transport layers like the BSD socket API typically do not support a payload that big. For the moment, data chunks that exceed this limit result in returning an error.</td>
</tr>
</tbody>
</table>
## 37.7 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_WEBSOCKET_Close()</td>
<td>Sends a WebSocket close frame to the peer.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_DiscardMessage()</td>
<td>Discards all frames that belong to the currently processed message.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_GenerateAcceptKey()</td>
<td>Generates the value to send back for the Sec-WebSocket-Accept field when accepting the connection.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_InitClient()</td>
<td>Initializes a client side WebSocket context.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_InitServer()</td>
<td>Initializes a server side WebSocket context.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_Recv()</td>
<td>Receives application data until the end (FIN flagged) frame of a message has been used up (all data read).</td>
</tr>
<tr>
<td>IP_WEBSOCKET_Send()</td>
<td>Sends application data.</td>
</tr>
<tr>
<td>IP_WEBSOCKET_WaitForNextMessage()</td>
<td>Waits until the next message is received.</td>
</tr>
</tbody>
</table>
37.7.1 IP_WEBSOCKET_Close()

Description
Sends a WebSocket close frame to the peer.

Prototype

```c
int IP_WEBSOCKET_Close(IP_WEBSOCKET_CONTEXT * pContext,
                       char * sReason,
                       U16 CloseCode);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>sReason</td>
<td>Reason for the close. Can be NULL.</td>
</tr>
<tr>
<td></td>
<td>• For a client context this needs to point to RAM</td>
</tr>
<tr>
<td></td>
<td>as the data will be encoded at its source location before it is sent.</td>
</tr>
<tr>
<td>CloseCode</td>
<td>IP_WEBSOCKET_CLOSE_CODE_.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>All data sent.</td>
</tr>
<tr>
<td>= 0</td>
<td>No data sent (typically with non-blocking sockets). Can indicate an unexpected/early close from the peer. Do the same call again. If it really was a close from peer a second call should return with an error. This return value depends on how the TCP/IP stack treats this case.</td>
</tr>
<tr>
<td>= IP_WEBSOCKET_ERR_AGAIN</td>
<td>No data (payload) sent, do the same call again.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Additional information

Return values 0 and IP_WEBSOCKET_ERR_AGAIN are typically only returned when the socket interface is used in non-blocking mode.

A close message is the last message received from a peer. It is unlikely and even wrong if the peer would send us any message after a close message.

Once a close message has been received from the peer, a close message shall be sent if not done before and then the network connection shall be closed.

For a server side the WebSocket close message shall be sent and then the network connection shall be closed without waiting for a close message from the peer.
37.7.2   IP_WEBSOCKET_DiscardMessage()

Description
Discards all frames that belong to the currently processed message.

Prototype

```c
int IP_WEBSOCKET_DiscardMessage(IP_WEBSOCKET_CONTEXT * pContext);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt; 0</td>
<td>O.K., message discarded.</td>
</tr>
<tr>
<td>= 0</td>
<td>Connection closed.</td>
</tr>
<tr>
<td>&lt; 0</td>
<td>Error.</td>
</tr>
</tbody>
</table>

Additional information

There are two types of WebSocket messages that can be received by the application (text and binary). Only a text or binary message that has been previously identified by IP_WEBSOCKET_WaitForNextMessage() will be discarded.

After discarding a message, the next message needs to be identified by calling IP_WEBSOCKET_WaitForNextMessage().
37.7.3  IP_WEBSOCKET_GenerateAcceptKey()

Description
Generates the value to send back for the Sec-WebSocket-Accept field when accepting the connection.

Prototype

```c
int IP_WEBSOCKET_GenerateAcceptKey ( void * pSecWebSocketKey,
                                       int SecWebSocketKeyLen,
                                       void * pBuffer,
                                       int BufferSize);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pSecWebSocketKey</td>
<td>Pointer to a buffer containing the string of the Sec-WebSocket-Key from the HTTP request.</td>
</tr>
<tr>
<td>SecWebSocketKeyLen</td>
<td>Number of characters of the Sec-WebSocket-Key (without string termination).</td>
</tr>
<tr>
<td>pBuffer</td>
<td>Buffer where to store the accept key.</td>
</tr>
<tr>
<td>BufferSize</td>
<td>Size of buffer where to store the accept key.</td>
</tr>
</tbody>
</table>

Return value

- > 0     Length of accept key.
- = 0     Error, buffer not big enough.

Additional information

The calculation of the accept key is done by the following steps:
- Adding the base64 encoded Sec-WebSocket-Key to a new SHA-1 hash.
- Adding the string “258EAFA5-E914-47DA-95CA-C5AB0DC85B11” to the SHA-1 hash.
- Base64 encode the resulting SHA-1 hash. This is the accept key to send back with the Sec-WebSocket-Accept field.
37.7.4  IP_WEBSOCKET_InitClient()

Description
Initializes a client side WebSocket context.

Prototype

```c
void  IP_WEBSOCKET_InitClient (       IP_WEBSOCKET_CONTEXT       *  pContext ,
                              const  IP_WEBSOCKET_TRANSPORT_API *  pAPI ,
                              IP_WEBSOCKET_CONNECTION    *  pConnection );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>pAPI</td>
<td>Application API to use for WebSocket communication.</td>
</tr>
<tr>
<td>pConnection</td>
<td>Transport connection handle.</td>
</tr>
</tbody>
</table>
37.7.5  IP_WEBSOCKET_InitServer()

**Description**
Initializes a server side WebSocket context.

**Prototype**

```c
void IP_WEBSOCKET_InitServer(
    IP_WEBSOCKET_CONTEXT    *  pContext,
    const IP_WEBSOCKET_TRANSPORT_API *  pAPI,
    IP_WEBSOCKET_CONNECTION    *  pConnection);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>pAPI</td>
<td>Application API to use for WebSocket communication.</td>
</tr>
<tr>
<td>pConnection</td>
<td>Transport connection handle.</td>
</tr>
</tbody>
</table>
37.7.6  IP_WEBSOCKET_Recv()

Description
Receives application data until the end (FIN flagged) frame of a message has been used up (all data read).

Prototype

```c
int IP_WEBSOCKET_Recv(IP_WEBSOCKET_CONTEXT * pContext,
                        void                  * pData,
                        int                     NumBytes);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>pData</td>
<td>Where to store the received data.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Maximum amount of data to receive.</td>
</tr>
</tbody>
</table>

Return value

- $> 0$  Amount of data received.
- $= 0$  Connection closed.
- $< 0$  Error. IP_WEBSOCKET_ERR_AGAIN: Repeat the call (typically with non-blocking sockets). IP_WEBSOCKET_ERR_ALL_DATA_READ: All data of the current message has been read. Call IP_WEBSOCKET_WaitForNextMessage() to check for another message.

Additional information

The WebSocket receive function follows the concept of a blocking socket recv call. Once called it will block until either at least one byte of application data from the current message is available or the peer of the WebSocket connection sends a close frame or an error occurs.

This function is able to receive continuous data from multiple WebSocket frames of the same message. In case this function is called with no more data left in the current frame and the frame was the last of the current message (FIN flag set), the error code IP_WEBSOCKET_ERR_ALL_DATA_READ is returned. In this case IP_WEBSOCKET_WaitForNextMessage() needs to be called before further recv calls.
37.7.7 IP_WEBSOCKET_Send()

Description
Sends application data.

Prototype

```
int IP_WEBSOCKET_Send ( IP_WEBSOCKET_CONTEXT * pContext,
                        void                  * pData,
                        int                     NumBytes,
                        U8                     MessageType,
                        U8                     SendMore);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>pData</td>
<td>Data to send.</td>
</tr>
<tr>
<td></td>
<td>• For a client context this needs to point to RAM as the data will be</td>
</tr>
<tr>
<td></td>
<td>encoded at its source location before it is sent.</td>
</tr>
<tr>
<td>NumBytes</td>
<td>Amount of data to send.</td>
</tr>
<tr>
<td>MessageType</td>
<td>IP_WEBSOCKET_FRAME_TYPE_TEXT or IP_WEBSOCKET_FRAME_TYPE_BINARY.</td>
</tr>
<tr>
<td>SendMore</td>
<td>• 0: Send a single frame/part message or the last frame/part of a message</td>
</tr>
<tr>
<td></td>
<td>sent in multiple calls.</td>
</tr>
<tr>
<td></td>
<td>• 1: Send a message in multiple frames/parts. This is not the last</td>
</tr>
<tr>
<td></td>
<td>frame/part of the message.</td>
</tr>
</tbody>
</table>

Return value

- \( = \) NumBytes: All data sent.
- \( = 0 \): No data sent (typically with non-blocking sockets).
- \( = \) IP_WEBSOCKET_ERR_AGAIN: No data (payload) sent, do the same call again.
- \( < 0 \): Error.

Additional information

Return values 0 and IP_WEBSOCKET_ERR_AGAIN are typically only returned when the socket interface is used in non-blocking mode.
37.7.8  IP_WEBSOCKET_WaitForNextMessage()

Description

Waits until the next message is received.

Prototype

```c
int IP_WEBSOCKET_WaitForNextMessage(IP_WEBSOCKET_CONTEXT * pContext,
                                      U8                   * pMessageType);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>pMessageType</td>
<td>Where to store the read message type. Can be NULL.</td>
</tr>
</tbody>
</table>

Return value

- > 0  O.K., next message received.
- = 0   Connection closed.
- = IP_WEBSOCKET_ERR_AGAIN  Repeat the call (typically with non-blocking sockets).
- < 0   Error.

Additional information

The return value IP_WEBSOCKET_ERR_AGAIN is typically only returned when the socket interface is used in non-blocking mode.

O.K. is returned for all message types received but the application has to handle only what it is interested in (text, binary or close messages).

All other message types that are effective control frames are handled internal. Messages of type text or binary that are not handled by the application will be discarded on the next call of this function.
37.8 Data structures

37.8.1 Structure IP_WEBSOCKET_TRANSPORT_API

Description
Used to provide an interface to external TCP/IP transport functions.

Prototype

```c
typedef struct IP_WEBSOCKET_TRANSPORT_API_STRUCT IP_WEBSOCKET_TRANSPORT_API;

struct IP_WEBSOCKET_TRANSPORT_API_STRUCT {
    int (*pfRecv)( IP_WEBSOCKET_CONTEXT* pContext,
                  IP_WEBSOCKET_CONNECTION* pConnection,
                  void* pData,
                  unsigned NumBytes);
    int (*pfSend)(        IP_WEBSOCKET_CONTEXT* pContext,
                     IP_WEBSOCKET_CONNECTION* pConnection,
                     const void* pData,
                     unsigned NumBytes);
    U32 (*pfGenMaskKey)(void);
};
```

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pfRecv</td>
<td>Callback used to receive data via a TCP/IP stack.</td>
</tr>
<tr>
<td>- pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>- pConnection</td>
<td>Connection handle of the TCP/IP stack. Typically a socket handle or SSL session handle.</td>
</tr>
<tr>
<td>- pData</td>
<td>Where to store the received data.</td>
</tr>
<tr>
<td>- NumBytes</td>
<td>Maximum amount of data to receive.</td>
</tr>
<tr>
<td>pfSend</td>
<td>Callback used to send data via a TCP/IP stack.</td>
</tr>
<tr>
<td>- pContext</td>
<td>WebSocket connection context.</td>
</tr>
<tr>
<td>- pConnection</td>
<td>Connection handle of the TCP/IP stack. Typically a socket handle is used.</td>
</tr>
<tr>
<td>- pData</td>
<td>Data to send.</td>
</tr>
<tr>
<td>- NumBytes</td>
<td>Amount of data to send.</td>
</tr>
</tbody>
</table>
37.9 Resource usage

The ROM usage depends on the compiler options, the compiler version and the used CPU. The memory requirements of the WebSocket add-on presented in the tables below have been measured on a Cortex-M4 system. Details about the further configuration can be found in the sections of the specific example.

37.9.1 ROM usage on a Cortex-M4 system

The following resource usage has been measured on a Cortex-M4 system using SEGGER Embedded Studio V3.10e, size optimization.

<table>
<thead>
<tr>
<th>Addon</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP WebSocket protocol</td>
<td>approximately 1.7 kBytes</td>
</tr>
</tbody>
</table>

37.9.2 RAM usage

While the WebSocket add-on itself does not require any RAM at all, a context element per connection is required.

<table>
<thead>
<tr>
<th>Addon</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP WebSocket context</td>
<td>approximately 30 Bytes</td>
</tr>

</table>
Chapter 38
Profiling with SystemView

This chapter describes how to configure and enable profiling of embOS/IP using SystemView.
38.1 Profiling overview

embOS/IP is instrumented to generate profiling information of API functions and driver-level functions.

These profiling information expose the run-time behavior of embOS/IP in an application, recording which API functions have been called, how long the execution took, and revealing which driver-level functions have been called by API functions or events like interrupts.

The profiling information is recorded using SystemView.

SystemView is a real-time recording and visualization tool for profiling data. It exposes the true run-time behavior of a system, going far deeper than the insight provided by debuggers. This is particularly effective when developing and working with complex systems comprising an OS with multiple threads and interrupts, and one or more middleware components.

SystemView can ensure a system performs as designed, can track down inefficiencies, and show unintended interactions and resource conflicts.

The recording of profiling information with SystemView is minimally intrusive to the system and can be done on virtually any system. With SEGGER’s Real Time Technology (RTT) and a J-Link, SystemView can record data in real-time and analyze the data live, while the system is running.

The embOS/IP profiling instrumentation can be easily configured and set up.
38.2 Additional files for profiling

Additional files are required on target and PC side for full functionality of SystemView.

38.2.1 Additional files on target side

The SystemView module needs to be added to the application to enable profiling. If not already part of the project, download the sources from https://www.segger.com/systemview.html and add them to the project.

Also make sure that IP_SYSVIEW.c from the /IP/ directory is included in the project.

38.2.2 Additional files on PC side

For fully functional and readable outputs in the SystemView PC application, a description file for the corresponding middleware is required. This description file extends the values sent from the target to fully readable text outputs.

While SystemView already comes with the most recent description files at the time the SystemView release has been built, these files might not be the latest available. The latest SystemView description files can be found in the embOS/IP shipment in the folder /Shared/SystemView/Description/. You can copy these files over to the Description folder that comes with the SystemView package.

The version at the end of the SystemView description file does not have to match the exact version of the middleware it is used with. They are valid from this version onwards until a description file for a newer version is required.
38.3 Enable profiling

Profiling can be included or excluded at compile-time and enabled at run-time. When profiling is excluded, no additional overhead in performance or memory usage is generated. Even when profiling is enabled the overhead is minimal, due to the efficient implementation of SystemView.

To include profiling, define \texttt{IP\_SUPPORT\_PROFILE} as 1 in the embOS/IP configuration (\texttt{IP\_Conf.h}) or in the project preprocessor defines.

Per default profiling is included when the global define \texttt{SUPPORT\_PROFILE} is set.

Profiling the end of function calls may be enabled or disabled separately with the define \texttt{IP\_SUPPORT\_PROFILE\_END\_CALL}. When profiling is enabled it may be defined as 0 to disable recording end of function calls and therefore save bandwidth.

```c
#if defined(SUPPORT_PROFILE) && (SUPPORT_PROFILE)
    #ifndef IP_SUPPORT_PROFILE
    #define IP_SUPPORT_PROFILE 1
    #endif
#endif

#if defined(IP_SUPPORT_PROFILE)
    #ifndef IP_SUPPORT_PROFILE_END_CALL
    #define IP_SUPPORT_PROFILE_END_CALL IP_SUPPORT_PROFILE
    #endif
#elif defined(IP_SUPPORT_PROFILE_END_CALL)
    #define IP_SUPPORT_PROFILE_END_CALL 0
#endif
```

To enable profiling at run-time, \texttt{IP\_SYSVIEW\_Init()} needs to be called. Profiling can be enabled at any time, it is recommended to do this in the user-provided configuration \texttt{IP\_X\_Config()}:

```c
/*********************************************************************/
/* */
/* IP_X_Config() */
*/
void IP_X_Config(void) {
    ...
    #if IP_SUPPORT_PROFILE
        IP_SYSVIEW_Init();
    #endif
    ...
}
```
38.4 Recording and analyzing profiling information

When profiling is included and enabled embOS/IP generates profiling events. On a system which supports RTT (i.e. ARM Cortex-M and Renesas RX) the data can be read and analyzed with SystemView and a J-Link. Connect the J-Link to the target system using the default debug interface and start the SystemView host application. If the system does not support RTT, SystemView can be configured for single-shot or postmortem mode. Please refer to the SystemView User Manual for more information.
Chapter 39
Debugging

embOS/IP comes with various debugging options. These include optional warning and log outputs, as well as other run-time options which perform checks at run time as well as options to drop incoming or outgoing packets to test stability of the implementation on the target system.
39.1 Message output

The debug builds of embOS/IP include a fine grained debug system which helps to analyze the correct implementation of the stack in your application. All modules of the TCP/IP stack can output logging and warning messages via terminal I/O, if the specific message type identifier is added to the log and/or warn filter mask. This approach provides the opportunity to get and interpret only the logging and warning messages which are relevant for the part of the stack that you want to debug.

By default, all warning messages are activated in all embOS/IP sample configuration files. All logging messages are disabled except for the messages from the initialization and the DHCP setup phase.
39.2 Testing stability

embOS/IP allows to define drop-rates for both receiver and transmitter. This feature can be used to simulate packet loss. Packet loss means that one or more packets fail to reach their destination. Packet loss can be caused by a number of factors (for example, signal degradation over the network medium, faulty networking hardware, error in network applications, etc.).

Two variables, IP_TxDropRate and IP_RxDropRate, are implemented to define the drop-rate while the target is running. There is no need to recompile the stack. The default value of these variables is 0, which means that no packets should be dropped from the stack. Any other value of n (for example, n = 2, 3, ...) will drop every n-th packet. This allows testing the reliability of communication and performance drop. A good value to test the stability is typically around 50.

To change the value of IP_TxDropRate and/or IP_RxDropRate the following steps are required:

1. Download your embOS/IP application into the target.
2. Start your debugger.
3. Open the Watch window and add one or both drop-rate variables.
4. Assign the transmit and/or receive drop-rate and start your application.
39.3 API functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_Log()</td>
<td>This function is called by the stack in debug builds with log output.</td>
</tr>
<tr>
<td>IPWarn()</td>
<td>This function is called by the stack in debug builds with log output.</td>
</tr>
<tr>
<td>IP_Logf_Application()</td>
<td>Outputs a formatted log message of type IP_MTYPE_APPLICATION if the filter allows it.</td>
</tr>
<tr>
<td>IP_Warnf_Application()</td>
<td>Outputs a formatted warn message of type IP_MTYPE_APPLICATION if the filter allows it.</td>
</tr>
</tbody>
</table>

Filter functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_AddLogFilter()</td>
<td>Adds an additional filter condition to the mask which specifies the logging messages that should be displayed.</td>
</tr>
<tr>
<td>IP_AddWarnFilter()</td>
<td>Adds an additional filter condition to the mask which specifies the warning messages that should be displayed.</td>
</tr>
<tr>
<td>IP_SetLogFilter()</td>
<td>Sets a mask that defines which logging message should be logged.</td>
</tr>
<tr>
<td>IP_SetWarnFilter()</td>
<td>Sets a mask that defines which warning messages should be logged.</td>
</tr>
</tbody>
</table>

General debug functions/macros

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_PANIC()</td>
<td>Called if the stack encounters a critical situation.</td>
</tr>
<tr>
<td>IP_Panic()</td>
<td>This function is called if the stack encounters a critical situation.</td>
</tr>
</tbody>
</table>
39.3.1  IP_Log()

Description
This function is called by the stack in debug builds with log output. In a release build, this function may not be linked in.

Prototype

\texttt{void IP\_Log(const char * s);} \\

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{s}</td>
<td>String to output.</td>
</tr>
</tbody>
</table>

Additional information
Interrupts and task switches printf() has a re-entrance problem on a lot of systems if interrupts are not disabled. Strings to output would be scrambled if during an output from a task an output from an interrupt would take place. In order to avoid this problem, interrupts are disabled.
39.3.2  IP_Warn()

Description
This function is called by the stack in debug builds with log output. In a release build, this function may not be linked in.

Prototype

```c
void IP_Warn (const char * s);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>String to output.</td>
</tr>
</tbody>
</table>

Additional information
Interrupts and task switches printf() has a re-entrance problem on a lot of systems if interrupts are not disabled. Strings to output would be scrambled if during an output from a task an output from an interrupt would take place. In order to avoid this problem, interrupts are disabled.
39.3.3  IP_Logf_Application()

Description
Outputs a formatted log message of type IP_MTYPE_APPLICATION if the filter allows it.

Prototype

```c
void IP_Logf_Application(const char * sFormat,
                          ...);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sFormat</td>
<td>String to output that might contain placeholders.</td>
</tr>
</tbody>
</table>
39.3.4 IP_Warnf_Application()

Description
Outputs a formatted warn message of type IP_MTYPE_APPLICATION if the filter allows it.

Prototype

```c
void IP_Warnf_Application(const char * sFormat,
                         ...);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sFormat</td>
<td>String to output that might contain placeholders.</td>
</tr>
</tbody>
</table>
39.3.5  IP_AddLogFilter()

Description
Adds an additional filter condition to the mask which specifies the logging messages that should be displayed.

Prototype

```c
void IP_AddLogFilter(U32 TypeMask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeMask</td>
<td>Bitwise-OR'ed message type(s) like IP_MTYPE_INIT.</td>
</tr>
</tbody>
</table>

Example

```c
IP_AddLogFilter(IP_MTYPE_DRIVER); // Activate driver logging messages
```
39.3.6  IP_AddWarnFilter()

Description
Adds an additional filter condition to the mask which specifies the warning messages that should be displayed.

Prototype

```c
void IP_AddWarnFilter(U32 TypeMask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeMask</td>
<td>Bitwise-OR'd message type(s) like IP_MTYPE_INIT.</td>
</tr>
</tbody>
</table>

Example

```c
IP_AddWarnFilter(IP_MTYPE_DRIVER); // Activate driver warning messages
```
39.3.7  IP_SetLogFilter()

Description
Sets a mask that defines which logging message should be logged. Logging messages are only available in debug builds of embOS/IP.

Prototype

```c
void IP_SetLogFilter(U32 TypeMask);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeMask</td>
<td>Bitwise-OR’d message type(s) like IP_MTYPE_INIT.</td>
</tr>
</tbody>
</table>

Additional information

This function should be called from IP_X_Config(). By default, the filter condition IP_MTYPE_INIT, IP_MTYPE_DHCP and IP_MTYPE_LINK_CHANGE are set.
39.3.8  IP_SetWarnFilter()

Description
Sets a mask that defines which warning messages should be logged. Warning messages
are only available in debug builds of embOS/IP.

Prototype

`void IP_SetWarnFilter(U32 TypeMask);`

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TypeMask</td>
<td>Bitwise-OR’d message type(s) like IP_MTYPE_INIT.</td>
</tr>
</tbody>
</table>

Additional information

This function should be called from `IP_X_Config()`. By default, all filter conditions are set.
39.3.9   IP_PANIC()

Description
This macro is called by the stack code when it detects a situation that should not be occurring and the stack can not continue. The intention for the IP_PANIC() macro is to invoke whatever debugger may be in use by the programmer. In this way, it acts like an embedded breakpoint.

Prototype

\begin{verbatim}
IP_PANIC ( const char * sError );
\end{verbatim}

Additional information
This macro maps to a function in debug builds only. If IP_DEBUG > 0, the macro maps to the stack internal function void IP_Panic ( const char * sError ). IP_Panic() disables all interrupts to avoid further task switches, outputs sError via terminal I/O and loops forever. When using an emulator, you should set a breakpoint at the beginning of this routine or simply stop the program after a failure. The error code is passed to the function as parameter.

In a release build, this macro is defined empty, so that no additional code will be included by the linker.
39.3.10 IP_Panic()

**Description**
This function is called if the stack encounters a critical situation. In a release build, this function may not be linked in.

**Prototype**

```c
void IP_Panic(const char * s);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>s</code></td>
<td>String to output.</td>
</tr>
</tbody>
</table>
39.4 Message types

The same message types are used for log and warning messages. Separate filters can be used for both log and warnings. For details, refer to `IP_SetLogFilter` on page 1173 and `IP_SetWarnFilter` on page 1174 as well as `IP_AddLogFilter` on page 1171 and `IP_AddLogFilter` on page 1171 for more information about using the message types.

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_MTYPE_INIT</td>
<td>Activates output of messages from the initialization of the stack that should be logged.</td>
</tr>

<td>Activates output of messages from address conflict module that should be logged.</td>
</tr>
</tbody>
</table>
39.5 Using a network sniffer to analyze communication problems

Using a network sniffer to analyze your local network traffic may give you a deeper understanding of the data that is being sent in your network. For this purpose you can use several network sniffers. Some of them are available for free such as Wireshark. An example of a network sniff using Wireshark is shown in the screenshot below:
CHAPTER 39  Using a network sniffer to analyze communication problems
Chapter 40

OS integration

embOS/IP is designed to be used in a multitasking environment. The interface to the operating system is encapsulated in a single file, the IP/OS interface. For embOS, all functions required for this IP/OS interface are implemented in a single file which comes with embOS/IP.

This chapter provides descriptions of the functions required to fully support embOS/IP in multitasking environments.
40.1 OS integration general information

The complexity of the IP/OS Interface depends on the task model selected. Refer to Tasks and interrupt usage on page 44 for detailed informations about the different task models. All OS interface functions for embOS are implemented in IP_OS_embOS.c which can be found in the sample folder of the shipment.

The IP/OS interface and its functions are not meant to be used in an application. Their purpose is to provide an OS interface for embOS/IP and calling them from an application might confuse the internal mechanics of embOS/IP.

</tr>
</tbody>
</table>
Function | Description
--- | ---
IP_OS_SignalItem() | Sets an object to signaled state, or resumes tasks which are waiting at the event object.

### 40.1.1 Examples

**OS interface routine for embOS**

All OS interface routines are implemented in `IP_OS_embOS.c` which is located in the `Sample\IP\OS\` folder of the IP stack.
40.1.2   IP_OS_Delay()

Description
Blocks the calling task for a given time.

Prototype

void  IP_OS_Delay(unsigned  ms);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms</td>
<td>Time to block in system ticks (typically 1ms).</td>
</tr>
</tbody>
</table>
40.1.3 IP_OS_DisableInterrupt()

Description
Disables interrupts to lock against calls from interrupt routines.

Prototype

```c
void IP_OS_DisableInterrupt(void);
```
40.1.4 IP_OS_EnableInterrupt()

Description
Enables interrupts that have previously been disabled.

Prototype

```c
void IP_OS_EnableInterrupt(void);
```
40.1.5  IP_OS_GetTime32()

Description
Return the current system time in ms; The value will wrap around after approximately 49.7
days; This is taken into account by the stack.

Prototype
U32 IP_OS_GetTime32(void);

Return value
U32 timestamp in system ticks (typically 1ms).
40.1.6 IP_OS_Init()

Description

Initialize (create) all objects required for task synchronization; These are 2 events (for IP_Task and RxTask) and one semaphore for protection of critical code which may not be executed from multiple task at the same time.

Prototype

```c
void IP_OS_Init(void);
```
40.1.7  IP_OS_Lock()

Description
The stack requires a single lock, typically a resource semaphore or mutex; This function
locks this object, guarding sections of the stack code against other threads; If the entire
stack executes from a single task, no functionality is required here.

Prototype

```c
void IP_OS_Lock(void);
```
40.1.8  IP_OS_Unlock()

Description

Unlocks the single lock, locked by a previous call to IP_OS_Lock() and signals the IP_Task() if a packet has been freed.

Prototype

void IP_OS_Unlock(void);
40.1.9  IP_OS_SignalNetEvent()

Description
Wakes the IP Task if it is waiting for a NET-event or timeout in the function IP_OS_WaitNetEvent().

Prototype

\texttt{void IP_OS_SignalNetEvent(void);}

Additional information

See \texttt{IP_OS_WaitNetEvent()} regarding why we are using task events.
40.1.10 IP_OS_WaitNetEvent()

Description
Called from IP_Task() only; Blocks until the timeout expires or a NET-event occurs, meaning IP_OS_SignalNetEvent() is called from an other task or ISR.

Prototype

```c
void IP_OS_WaitNetEvent(unsigned ms);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ms</td>
<td>Timeout for waiting in system ticks (typically 1ms).</td>
</tr>
</tbody>
</table>

Additional information

For the IP_Task() task events are used as they are using less overhead and are slightly faster using event objects. However as the task control block needs to be known the following rare case might occur:

- IP_Init() is done and Rx interrupts are enabled.
- IP_Task() which runs a loop of IP_Exec(); IP_OS_WaitNetEvent() gets interrupted before IP_OS_WaitNetEvent() can set IP_OS_pIPTask.
- The Rx interrupt now calls IP_OS_SignalNetEvent() but actually does not signal anything as IP_OS_pIPTask is still NULL.
- One interrupt might get lost which is not a problem for the IP_Task() as it will get woken up regularly anyhow or at least with the second Rx event.
40.1.11  IP_OS_SignalRxEvent()

Description
Called by an interrupt to signal that the IP_RxTask() needs to check for new received packets.

Prototype

```c
void IP_OS_SignalRxEvent(void);
```

Additional information

See IP_OS_WaitRxEvent() regarding task event vs. event object usage.
40.1.12  IP_OS_WaitRxEvent()

Description
Called by the IP_RxTask() whenever idle (no more packets in the In-Fifo).

Prototype
void  IP_OS_WaitRxEvent ( void );

Additional information
See IP_OS_WaitNetEvent() regarding problems that might occur when using task events. The same problematic applies to the IP_RxTask() but as this is treated like an interrupt we do not use a fallback activation each x seconds. Therefore we use event objects in all other cases which are always valid after IP_Init() and can be signaled before being waited on. In this case the wait will simply run through this time.
40.1.13  IP_OS_WaitItem()

Description
Suspend a task which needs to wait for an object; This object is identified by a pointer to it and can be of any type, for example socket.

Prototype

```c
void IP_OS_WaitItem(void * pWaitItem);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pWaitItem</td>
<td>Item to wait for.</td>
</tr>
</tbody>
</table>

Additional information
Function is called from an application task.
40.1.14 IP_OS_WaitItemTimed()

Description
Suspend a task which needs to wait for an object; this object is identified by a pointer to it and can be of any type, for example a socket.

Prototype

```c
void IP_OS_WaitItemTimed(void * pWaitItem,
                         unsigned Timeout);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pWaitItem</td>
<td>Item to wait for.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Timeout for waiting in system ticks (typically 1ms).</td>
</tr>
</tbody>
</table>

Additional information
Function is called from an application task and is locked in every case.
40.1.15  IP_OS_SignalItem()

Description
Sets an object to signaled state, or resumes tasks which are waiting at the event object.

Prototype

```c
void IP_OS_SignalItem(void * pWaitItem);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pWaitItem</td>
<td>Item to signal.</td>
</tr>
</tbody>
</table>

Additional information

Function is called from a task, not an ISR and is locked in every case.
Chapter 41

Performance & resource usage

This chapter covers the performance and resource usage of embOS/IP. It contains information about the memory requirements in typical systems which can be used to obtain sufficient estimates for most target systems.
**41.1 embOS/IP Memory footprint**

embOS/IP is designed to fit many kinds of embedded design requirements. Several features can be excluded from a build to get a minimal system. Note that the values are only valid for the given configurations.

**41.1.1 embOS/IP on ARM7 system**

The following table shows the hardware and the toolchain details of the project:

<table>
<thead>
<tr>
<th>Detail</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>ARM7</td>
</tr>
<tr>
<td>Tool chain</td>
<td>IAR Embedded Workbench for ARM V6.30.6</td>
</tr>
<tr>
<td>Model</td>
<td>ARM7, Thumb instructions; no interwork;</td>
</tr>
<tr>
<td>Compiler options</td>
<td>Highest size optimization;</td>
</tr>
</tbody>
</table>

**41.1.1.1 ROM usage ARM7**

The following table shows the ROM requirement of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP - complete stack</td>
<td>approximately 19.0 kBytes</td>
</tr>
</tbody>
</table>

**41.1.1.2 RAM usage ARM7**

The following table shows the RAM requirement of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP - complete stack w/o buffers</td>
<td>approximately 1.5 kBytes</td>
</tr>
</tbody>
</table>
41.1.2 embOS/IP on Cortex-M3 system

The following table shows the hardware and the toolchain details of the project:

<table>
<thead>
<tr>
<th>Detail</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>Cortex-M3</td>
</tr>
<tr>
<td>Tool chain</td>
<td>IAR Embedded Workbench for ARM V6.30.6</td>
</tr>
<tr>
<td>Model</td>
<td>Cortex-M3</td>
</tr>
<tr>
<td>Compiler options</td>
<td>Highest size optimization;</td>
</tr>
</tbody>
</table>

41.1.2.1 ROM usage Cortex-M3

The following table shows the ROM requirement of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>ROM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP - complete stack</td>
<td>approximately 19.0 kBytes</td>
</tr>
</tbody>
</table>

The memory requirements of a interface driver is about 1.5 - 2.0Kbytes.

41.1.2.2 RAM usage Cortex-M3

The following table shows the RAM requirement of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>RAM</th>
</tr>
</thead>
<tbody>
<tr>
<td>embOS/IP - complete stack w/o buffers</td>
<td>approximately 4.5 kBytes</td>
</tr>
</tbody>
</table>
41.2  embOS/IP performance

41.2.1  Performance on ARM7 system

<table>
<thead>
<tr>
<th>Detail</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>ARM7 with integrated MAC running with 48Mhz</td>
</tr>
<tr>
<td>Tool chain</td>
<td>IAR Embedded Workbench for ARM V6.30.6</td>
</tr>
<tr>
<td>Model</td>
<td>ARM7, Thumb instructions; no interwork;</td>
</tr>
<tr>
<td>Compiler options</td>
<td>Highest speed optimization;</td>
</tr>
</tbody>
</table>

**Memory configuration**

```c
#define ALLOC_SIZE 0xD000
IP_AddBuffers(12, 256);
IP_AddBuffers(18, mtu + 16);
IP_ConfTCPspace((mtu - 40) * 8, (mtu - 40) * 8);
```

**Driver configuration**

```c
#define NUM_RX_BUFFERS (2 * 12 + 1)
```

**Measurements**

The following table shows the send and receive speed of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>Speed [Mbytes per second]</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP - socket interface</td>
<td></td>
</tr>
<tr>
<td>Send speed</td>
<td>approximately 9.0</td>
</tr>
<tr>
<td>Receive speed</td>
<td>approximately 7.5</td>
</tr>
<tr>
<td>TCP - zero-copy interface</td>
<td></td>
</tr>
<tr>
<td>Send speed</td>
<td>approximately 9.0</td>
</tr>
<tr>
<td>Receive speed</td>
<td>approximately 11.7</td>
</tr>
</tbody>
</table>

The performance of any network will depend on several considerations, including the length of the cabling, the size of packets, and the amount of traffic.
41.2.2 Performance on Cortex-M3 system

<table>
<thead>
<tr>
<th>Detail</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU</td>
<td>Cortex-M3 with integrated MAC running with 96Mhz</td>
</tr>
<tr>
<td>Tool chain</td>
<td>IAR Embedded Workbench for ARM V6.30.6</td>
</tr>
<tr>
<td>Model</td>
<td>Cortex-M3</td>
</tr>
<tr>
<td>Compiler options</td>
<td>Highest speed optimization;</td>
</tr>
</tbody>
</table>

**Memory configuration**

```c
#define ALLOC_SIZE 0x10000
IP_AddBuffers(12, 256);
IP_AddBuffers(12, mtu + 16);
IP_ConfTCPSpace(9 * (mtu - 40), 9 * (mtu - 40));
```

**Driver configuration**

```c
#define NUM_RX_BUFFERS (36)
#define BUFFER_SIZE (256)
```

**Measurements**

The following table shows the send and receive speed of embOS/IP:

<table>
<thead>
<tr>
<th>Description</th>
<th>Speed [MBytes per second]</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP - socket interface</td>
<td></td>
</tr>
<tr>
<td>Send speed</td>
<td>approximately 9.4</td>
</tr>
<tr>
<td>Receive speed</td>
<td>approximately 11.7</td>
</tr>
<tr>
<td>TCP - zero-copy interface</td>
<td></td>
</tr>
<tr>
<td>Send speed</td>
<td>approximately 9.4</td>
</tr>
<tr>
<td>Receive speed</td>
<td>approximately 11.8</td>
</tr>
</tbody>
</table>

The performance of any network will depend on several considerations, including the length of the cabling, the size of packets, and the amount of traffic.
Chapter 42

Appendix A - File system abstraction layer
42.1 File system abstraction layer

This section provides a description of the file system abstraction layer used by embOS/IP applications which require access to a data storage medium. The file system abstraction layer is supplied with the embOS/IP web server and the embOS/IP FTP server.

Three file system abstraction layer implementations are available:

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IP_FS_emFile.c</td>
<td>Mapping of the embOS/IP file system abstraction layer functions to emFile functions.</td>
</tr>
<tr>
<td>IP_FS_ReadOnly.c</td>
<td>Implementation of a read-only file system. Typically used in a web server application.</td>
</tr>
<tr>
<td>IP_FS_Linux.c</td>
<td>Mapping of the embOS/IP file system abstraction layer functions to Linux file I/O functions.</td>
</tr>
<tr>
<td>IP_FS_Win32.c</td>
<td>Mapping of the embOS/IP file system abstraction layer functions to Windows file I/O functions.</td>
</tr>
</tbody>
</table>
42.2 File system abstraction layer function table

embOS/IP uses a function table to call the appropriate file system function.

Data structure

typedef struct {
    // Read only file operations. These have to be present on ANY file system,
    // even the simplest one.
    void * (*pfOpenFile) (const char * sFilename,
                           const char * sOpenFlags);
    int (*pfCloseFile) (void * hFile);
    int (*pfReadAt) (void * hFile,
                     void * pBuffer,
                     U32   Pos,
                     U32   NumBytes);
    long (*pfGetLen) (void * hFile);
    // Directory query operations.
    void (*pfForEachDirEntry) (void * pContext,
                               const char * sDir,
                               void (*pf) (void * pContext,
                                           void * pFileEntry));
    void (*pfGetDirEntryFileName) (void * pFileEntry,
                                    char * sFileName,
                                    U32 SizeOfBuffer);
    U32 (*pfGetDirEntryFileSize) (void * pFileEntry,
                                   U32   * pFileSizeHigh);
    int (*pfGetDirEntryFileTime) (void * pFileEntry);
    U32 (*pfGetDirEntryAttributes) (void * pFileEntry);
    // Write file operations.
    void * (*pfCreate) (const char * sFileName);
    void * (*pfDeleteFile) (const char * sFilename);
    int (*pfRenameFile) (const char * sOldFilename,
                          const char * sNewFilename);
    int (*pfWriteAt) (void * hFile,
                      void * pBuffer,
                      U32   Pos,
                      U32   NumBytes);
    // Additional directory operations
    int (*pfMKDir) (const char * sDirName);
    int (*pfRMDir) (const char * sDirName);
    // Additional operations
    int (*pfIsFolder) (const char * sPath);
    int (*pfMove) (const char * sOldFilename,
                   const char * sNewFilename);
} IP_FS_API;
## Elements of IP_FS_API

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Read only file system functions (required)</strong></td>
<td></td>
</tr>
<tr>
<td><code>pfOpenFile</code></td>
<td>Pointer to a function that creates/opens a file and returns the handle of these file.</td>
</tr>
<tr>
<td><code>pfCloseFile</code></td>
<td>Pointer to a function that closes a file.</td>
</tr>
<tr>
<td><code>pfReadAt</code></td>
<td>Pointer to a function that reads a file.</td>
</tr>
<tr>
<td><code>pfGetLen</code></td>
<td>Pointer to a function that returns the length of a file.</td>
</tr>
<tr>
<td><strong>Directory query operations</strong></td>
<td></td>
</tr>
<tr>
<td><code>pfForEachDirEntry</code></td>
<td>Pointer to a function which is called for each directory entry.</td>
</tr>
<tr>
<td><code>pfGetDirEntryFileName</code></td>
<td>Pointer to a function that returns the name of a file entry.</td>
</tr>
<tr>
<td><code>pfGetDirEntryFileSize</code></td>
<td>Pointer to a function that returns the size of a file.</td>
</tr>
<tr>
<td><code>pfGetDirEntryFileTime</code></td>
<td>Pointer to a function that returns the time-stamp of a file.</td>
</tr>
<tr>
<td><code>pfGetDirEntryAttributes</code></td>
<td>Pointer to a function that returns the attributes of a directory entry.</td>
</tr>
<tr>
<td><strong>Write file operations</strong></td>
<td></td>
</tr>
<tr>
<td><code>pfCreate</code></td>
<td>Pointer to a function that creates a file.</td>
</tr>
<tr>
<td><code>pfDeleteFile</code></td>
<td>Pointer to a function that deletes a file.</td>
</tr>
<tr>
<td><code>pfRenameFile</code></td>
<td>Pointer to a function that renames a file.</td>
</tr>
<tr>
<td><code>pfWriteAt</code></td>
<td>Pointer to a function that writes a file.</td>
</tr>
<tr>
<td><strong>Additional directory operations (optional)</strong></td>
<td></td>
</tr>
<tr>
<td><code>pfMKDir</code></td>
<td>Pointer to a function that creates a directory.</td>
</tr>
<tr>
<td><code>pfRMDir</code></td>
<td>Pointer to a function that deletes a directory.</td>
</tr>
<tr>
<td><strong>Additional operations (optional)</strong></td>
<td></td>
</tr>
<tr>
<td><code>pfIsFolder</code></td>
<td>Pointer to a function that checks if a path is a folder.</td>
</tr>
<tr>
<td><code>pfMove</code></td>
<td>Pointer to a function that moves a file or directory.</td>
</tr>
</tbody>
</table>
42.2.1 emFile interface

The embOS/IP web server and FTP server are shipped with an interface to emFile, SEGGER’s file system for embedded applications. It is a good example how to use a real file system with the embOS/IP web server / FTP server.

/* Excerpt from IP_FS_FS.c */

const IP_FS_API IP_FS_FS = {
    //
    // Read only file operations.
    //
    _FS_Open,
    _Close,
    _ReadAt,
    _GetLen,
    //
    // Simple directory operations.
    //
    _ForEachDirEntry,
    _GetDirEntryFileName,
    _GetDirEntryFileSize,
    _GetDirEntryFileTime,
    _GetDirEntryAttributes,
    //
    // Simple write type file operations.
    //
    _Create,
    _DeleteFile,
    _RenameFile,
    _WriteAt,
    //
    // Additional directory operations
    //
    _MKDir,
    _RMDir,
    //
    // Additional operations
    //
    _IsFolder,
    _Move
};

The emFile interface is used in all SEGGER Eval Packages.
42.2.2 Read-only file system

The embOS/IP web server and FTP server are shipped with a very basic implementation of a read-only file system. It is a good solution if you use embOS/IP without a real file system like emFile.

/* Excerpt from FS_RO.c */

const IP_WEBS_FS_API IP_FS_ReadOnly = {
    // Read only file operations.
    _FS_RO_FS_Open,
    _FS_RO_Close,
    _FS_RO_ReadAt,
    _FS_RO_GetLen,
    // Simple directory operations.
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    // Simple write type file operations.
    NULL,
    NULL,
    NULL,
    NULL,
    NULL,
    // Additional directory operations
    NULL,
    NULL,
    // Additional operations
    NULL,
    NULL
};

The read-only file system can be used in the example applications. It is sufficient, if the server should only deliver predefined files which are hardcoded in the sources of your application. It is used by default with the embOS/IP Web server example application.
42.2.3 Using the read-only file system

The read-only file system relies on an array of directory entries. A directory entry consists of a file name, a pointer to the data and an entry for the file size in bytes. This array of directory entries will be searched if a client requests a page.

```c
/* Excerpt from FS_RO.c */
typedef struct {
    const char * sFilename;
    const unsigned char * pData;
    unsigned int FileSize;
} DIR_ENTRY;

#include "webdata\generated\embos.h"     /* HTML page */
#include "webdata\generated\index.h"     /* HTML page */
#include "webdata\generated\segger.h"    /* segger.gif */
#include "webdata\generated\stats.h"     /* HTML page */

DIR_ENTRY _aFile[] = {
    /* file name     file array    current size */
    /* ---------     ----------    ------------  */
    {  "/embos.htm" ,    embos_file ,    EMBOS_SIZE   },
    {  "/index.htm" ,    index_file ,    INDEX_SIZE   },
    {  "/segger.gif" ,   segger_file ,   SEGGER_SIZE  },
    {  "/stats.htm" ,    stats_file ,    STATS_SIZE   },
    {  0  }
};
```

The example source files can easily be replaced. To build new contents for the read-only file system the following steps are required:

1. Copy the file which should be included in the read-only file system into the folder: `IP\IP_FS\FS_RO\webdata\html\`

2. Use an text editor (for example, Notepad) to edit the batch file `m.bat`. The batch file is located under: `IP\IP_FS\FS_RO\webdata\`. Add the file which should be built. For example: If your file is called `example.htm`, you have to add the following line to `m.bat`:

   ```bat
call cc example.htm
```

3. The `m.bat` calls `cc.bat`. `cc.bat` uses `bin2C.exe` an utility which converts any file to a standard C array. The new files are created in the folder:

   ```
   IP_FS_RO
   ```

4. Add the new source code file (for example, `example.c`) into your project. To add the new file to your read-only file system, you have to add the new file to the `DIR_ENTRY array _aFile[]` and include the generated header file (for example, `example.h`) in `FS_RO.c`. The expanded definition of `aFile[]` should look like:

```c
#include "webdata\generated\example.h"     /* NEW HTML page */

DIR_ENTRY _aFile[] = {
    /* file name     file array    current size */
    /* ---------     ----------    ------------  */
    {  "/embos.htm" ,    embos_file ,    EMBOS_SIZE   },
    {  "/index.htm" ,    index_file ,    INDEX_SIZE   },
    {  "/segger.gif" ,   segger_file ,   SEGGER_SIZE  },
    {  "/stats.htm" ,    stats_file ,    STATS_SIZE   },
    {  "/example.htm" ,  example_file ,  EXAMPLE_SIZE },
    {  0  }
};
```
5. Recompile your application.
42.2.4 Windows file system interface

The embOS/IP web server and FTP server is shipped with an implementation.

```c
const IP_FS_API IP_FS_Win32 = {
  //
  // Read only file operations.
  //
  _IP_FS_WIN32_Open,
  _IP_FS_WIN32_Close,
  _IP_FS_WIN32_ReadAt,
  _IP_FS_WIN32_GetLen,
  //
  // Simple directory operations.
  //
  _IP_FS_WIN32_ForeachDirEntry,
  _IP_FS_WIN32_GetDirEntryFileName,
  _IP_FS_WIN32_GetDirEntryFileSize,
  _IP_FS_WIN32_GetDirEntryFileTime,
  _IP_FS_WIN32_GetDirEntryAttributes,
  //
  // Simple write type file operations.
  //
  _IP_FS_WIN32_Create,
  _IP_FS_WIN32_DeleteFile,
  _IP_FS_WIN32_RenameFile,
  _IP_FS_WIN32_WriteAt,
  //
  // Additional directory operations
  //
  _IP_FS_WIN32_MakeDir,
  _IP_FS_WIN32_RemoveDir
  //
  // Additional operations
  //
  _IP_FS_WIN32_IsFolder,
  _IP_FS_WIN32_Move
};
```

The Windows file system interface is supplied with the FTP and the Web server add-on packages. It is used by default with the embOS/IP FTP server application.
Chapter 43

Support

This chapter should help if any problem occurs, e.g. with the hardware or the use of the embOS/IP functions, and describes how to contact the embOS/IP support.
43.1 Contacting support

If you are a registered embOS/IP user and you need to contact the embOS/IP support, please send the following information via email to support_embosip@segger.com:

- The embOS/IP version.
- Your embOS/IP registration number.
- If you are unsure about the above information, you may also use the name of the embOS/IP ZIP-file (which contains the above information).
- A detailed description of the problem.
- Optionally, a project with which we can reproduce the problem.
